Abstract—In this paper, we propose an efficient and secure patient-centric access control (PEACE) scheme for the emerging electronic health care (eHealth) system. In order to assure the privacy of patient personal health information (PHI), we define different access privileges to data requesters according to their roles, and then assign different attribute sets to the data requesters. By using these different sets of attributes, we construct the patient-centric access policies of patient PHI. The PEACE scheme can guarantee PHI integrity and confidentiality by adopting digital signature and pseudo-identity techniques. It encompasses identity based cryptography to aggregate remote patient PHI securely. Extensive security and performance analyses demonstrate that the PEACE scheme is able to achieve desired security requirements at the cost of an acceptable communication delay.

Index Terms—eHealth, security, privacy, attribute-based encryption, access control.

I. INTRODUCTION

ELECTRONIC health (eHealth) care system is a promising technology that has drawn extensive attention from both academia and industry recently. It describes the application of information and communication technologies across the whole range of function that affect the PHI. The eHealth system shows a high potential to improve the quality of diagnosis, reduce medical costs and help address the reliable and on-demand health care challenges posed by the aging society. Recent advances in Wireless Body Area Networks (WBANs) have made it possible to deploy bio-sensors on, in, or around the patient body and allow to continuous monitoring of physiological parameters (e.g., electrocardiogram (ECG), blood oxygen levels) with physical activities. It has lent great forces to the migration of health care system from hospital or care unit to the patient’s residence. Integrating this technology with the existing wireless technologies permits real-time mobile and permanent monitoring of patients, even during their daily normal activities. In such a heterogeneous wireless environment, secure communication of the patient PHI with integrity and confidentiality is an essential part of a reliable eHealth care system.

In addition, the eHealth care system needs to ensure the availability of PHI in electronic form adheres to the same levels of privacy and disclosure policy as applicable to present-day paper-based patient records accessible only from the physician’s office. Instead of storing the PHI locally, the recent advancement of cloud computing allows us to store all PHI centrally and ensures availability with reduces the capital and operational expenditures. Moving patients PHI into a cloud or in a central storage offers enormous conveniences to the eHealth care providers, since they don’t have to care about the complexities of direct hardware management [1]. However, patient’s privacy with proper access control of this available PHI is a growing concern in the eHealth care industry due to its direct involvement to human.

To address the patient privacy, we use attribute based ciphertext policy [2] to control the access to the patient private PHI and identity based encryption for secure communication between patient and eHealth care service provider. Our contributions are in three-fold: a) provide an architectural model of eHealth care system, b) show how PEACE provides a secure communication between remote patient and eHealth care provider, and c) present a patient-centric access control policy that helps PEACE to has more reliability. To construct this access control policy, we assign different attribute sets to data requesters based on their relation to the patient. For example, general users may know some common attributes of a patient, e.g., location, gender; patient’s relatives or health care givers may know more private information of a patient, likely medication details, patient date of birth, patient phone number, etc.; health insurance providers may have more privileges and can know patient health card number, Social Identification number, etc.

The remainder of this paper is organized as follows. Section II contains a brief description of related work. System model and security requirements are presented in Section III. Preliminaries such as bilinear pairing, security definition are introduced in Section IV. The proposed scheme is presented in Section V. Section VI and Section VII provide security analysis and performance analysis of the proposed PEACE scheme respectively. The paper is concluded in Section VIII.

II. RELATED WORK

Hybrid security policy for WBAN with Quality of Services (QoS) have recently been proposed for secure eHealth care system in [3]. R. Lu et al. presented a mobile health care social network, where two patients can communicate each other if they have the same symptoms [4]. Liang et. al.[5] presented a patient self-controllable access policy so that patients would have the primary control of the access to their own personal health information. Xiaodong et al. [6] proposed a privacy preserving scheme for health care that can effectively works against global adversary. Health records
sharing and integrating in health care cloud was discussed in [7]. In [1], Shucheng Yu et al. proposed a fine gained data access control in cloud computing based on key-policy based attribute based encryption (KP-ABE). Confidentiality of user access privilege and user secret key accountability can be achieved by their work. A mandatory access control model to protect patient’s metadata with privacy was presented in [8]. It was shown that the use of fragmentation after encryption greatly improves overall security because potential attackers need to compromise more data file to gain access. An efficient cloud storage sharing scheme was presented in [9]. The scheme worked on hierarchical identity based encryption, where intended recipients can share the file by using their private keys.

Attribute based encryption, a novel extension from identity based encryption by enabling expressive access policy to control the decryption process was presented in [2][10][11], where the encrypter encrypted the data by using some attributes. The attribute set was used to describe a user’s credentials.

III. SYSTEM MODEL AND SECURITY REQUIREMENTS

In this section, we define the system model and then describe the security requirements of the proposed PEACE scheme.

A. System Model

In our system model, the eHealth care service provider works as a trusted party, where a patient is registered. The encrypted data is stored in a centralize storage, health-cloud, for future access. Based on the major operations, the proposed scheme can be classified into four major steps, as shown in Fig 1.

Fig. 1. Secure data storage at Health-Cloud and secure data outsourcing

Step 1 (PHI collection): In this initial step, using different body sensors, PHI is sensed and ready to be transmitted to the trusted eHealth care service provider.

Step 2 (Secure data communication): In this step, public key cryptography is used to securely transfer collected PHI to the eHealth care service provider. Patient securely transfer a secret key to the trusted eHealth care provider, if he authorized the service provider to build-up the access tree.

Step 3 (PHI processing at eHealth care provider): After receiving the PHI securely, eHealth care service provider classifies the PHI based on the attributes set chosen by the patient. It then makes different privacy levels of data requesters based on their roles (e.g., level-1: general users, level-2: pharmacist, level-3: doctors, etc.) and assigns different set of attributes to these different levels.

Step 4 (Transfer PHI to the cloud storage and control access): After the data classification, encrypted data securely transfer to the cloud storage, shows as ‘Health Cloud’ in the Fig. 1. eHealth care service providers may operate either real-time or periodically based on the existing infrastructures. Data access requester sends their request to the cloud storage with a data block identity. They may also request for the corresponding attribute sets. In this case, the cloud storage provider communicates with the eHealth care service provider and verifies the authentication of the requesters. The data requester, as a node in the access tree (T), can decrypt a ciphertext if and only if other corresponding nodes (users) also cooperate with him, or he has all the attribute sets to complete the T.

In our system model, we classify the data requester as health worker, physicians, researchers, insurance companies, and agencies, etc. Some of them only need the accumulated number of patients in a specific area, some need disease related syndromes, age and gender specific characteristics, while others may need medication details. Fig. 2 shows possible access structures based on different privacy levels, where intermediate nodes work as a logic gates. For example, “2 of (location, gender, disease)” in the fig. 2(a) can be converted to “(location AND gender) OR (gender AND disease) OR (disease AND location)”.

Fig. 2. Access trees based on different data privacy level

B. Security Requirements

We aim at achieving the following security objectives.

1) **Patient-centric access control**: The system should provide patient-centric access control, where a patient can decides who can get the access to his/her stored PHI.

2) **Message integrity, source authentication and non-repudiation**: All accepted messages should be delivered unaltered, and the origin of the messages should be authenticated by the eHealth care service provider. To ensure the non-repudiation, the patient can not refute the validity of a PHI afterward.

3) **Prevention of Ciphertext-only attack**: The system should be secured enough to prevent recovery of the plaintext from a set of stored ciphertexts.

4) **Provide patient privacy**: Privacy is one of the important concerns from a patient perspective. Illegal disclosure and improper use of patient PHI can cause legal disputes and undesirable damaging in patient’s personal life.

5) **Resistant to collision attack**: Users can not get any access to the encrypted data even by sharing information in a group.

6) **Resistant to Denial-of-Service (DoS) attack**: The DoS attack may be caused due to the large groups of legitimate users access the eHealth care service provider at
the same time, or the attacker continuously launch false traffic with a high data rate. The system should ensure acceptable QoS level to resist the DoS attack.

IV. PRELIMINARIES

Since the bilinear pairing and the attribute based ciphertext policy work as the basis of our proposed scheme, we briefly review some related definitions and problem hardness, which closely follow those in [12].

Basic of Bilinear Pairing Consider two groups \( G_1 \), an additive, and \( G_2 \) a multiplicative group of the same prime order \( q \). Let \( P \) and \( Q \) be the two generators of \( G_1 \), and \( aP \) is the \( a \) times addition of \( P \). We can write the mapping \( e \) as \( e : G_1 \times G_1 \rightarrow G_2 \) which has the following properties:

1) Bilinear: \( \forall P, Q \in G_1, \forall a, b \in \mathbb{Z}_q^* \)
   \[ e(aP, bQ) = e(P, Q)^{ab} \]

2) Non-Degeneracy: \( P \neq 0 \Rightarrow e(P, P) \neq 1 \)

3) Symmetric: \( \forall P, Q \in G_1, e(P, Q) = e(Q, P) \).

4) Computability: \( e \) is efficiently computable.

Definition (BDH Parameter Generator): An algorithm \( Gen \) is called a BDH (Bilinear Diffe-Hellman) parameter generator if \( Gen \) takes a sufficient large security parameter \( K > 0 \) as input, runs in polynomial time in \( K \), outputs a prime number \( q \), the description of two groups \( G_1 \) and \( G_2 \) of order \( q \), and the description of a bilinear map \( e : G_1 \times G_1 \rightarrow G_2 \).

Definition (BDH Problem hardness): Given a random element \( P \in G_1 \), as well as \( aP, bP, cP \), for some random \( a, b, c \in \mathbb{Z}_q^* \), there is no efficient algorithm to compute \( e(P, P)^{abc} \in G_2 \) from \( P, aP, bP, cP \in G_1 \). This implies the hardness of the BDH in the group \( G_1 \) [12].

Definition (Access Structure [2]): Let \( \{a_1, a_2, \ldots, a_n\} \) be a set of health attributes. The sets \( \mathbb{A} (\mathbb{A}_1 \subset 2^{\{a_1, a_2, \ldots, a_n\}}) \) are called the authorized attributes set, and the sets not in \( \mathbb{A} \) are called the unauthorized sets. \( \mathbb{A} \) is monotone if \( \forall B, C : i f B \subseteq A \) and \( B \subseteq C \) then \( C \subseteq A \).

In the access-tree construction, ciphertexts are labeled with a set of descriptive authorized attributes. Secret keys are identified by an access tree in which each interior node of the tree is a threshold gate and the leaves are associated with attributes.

Setup(1^n): The probabilistic polynomial time (PPT) setup algorithm takes as input a security parameter \( 1^n \). It outputs the public parameters \( PK \) and a master key \( MK \) which is known only to the private key generator.

Encrypt(\( PKs, m, PKr \)): The encryption algorithm takes the public parameters of the sender and receiver and encrypt the message \( m \) by doing mapping and XOR operations. We use \( Encrypt_2(PK, M, A) \) function to encrypt the message \( M \) and store in the health cloud. This encryption algorithm takes the system public parameters \( PK \), a message \( M \), and an access structure \( A \) over the universe of health attributes. The encrypted ciphertext \( CT \) can only be decrypted if and only if the user possesses the set of health attributes that satisfy the access tree structure.

Decrypt(\( PK, C, d \)): The decryption algorithm takes as input the public parameter \( PK \), ciphertext \( C \), and the product of the receiver’s secret key and sender PK’s hash value. The health care provider uses this function to decrypt the encrypted message sent by the user for further processing. Another decryption function \( Decrypt_2(PK, CT, SK) \) takes as input the public parameters \( PK \), a ciphertext \( CT \), which contains the access policy \( \mathbb{A} \), and a secret key \( SK \), which is a private key for a set \( S \) of health attributes. If the set \( S \) of attributes satisfies the access structure \( \mathbb{A} \), the algorithm will decrypt the ciphertext and return the message \( M \).

The set of algorithms must satisfy the standard consistency requirements: For \( (PK, MK) \leftarrow Setup(1^n), (k, E) \leftarrow Encryption(PK, \gamma), D_\mathbb{A} \leftarrow KeyGen(PM, MK, \mathbb{A}) \) and \( \mathbb{A}(\gamma) = 1 \) (i.e. the attribute set \( \gamma \) satisfies the access structure \( \mathbb{A} \)), then we have \( Pr[Decrypt_2(PK, E(M), D_\mathbb{A}) = k] = 1 \).

V. PROPOSED PEACE SCHEME

The four major categories describe in the system model can be integrated into two major phases, as shown in Fig. 3.

A. Phase-A: secure data communication:

In the phase-A, the scheme defines the secure and privacy preserving communication between different eHealth users. Here, we describe the secure communication steps between a remote user and an eHealth service provider; communication among others e.g., eHealth service provider and the cloud storage or data requesters will follow the same steps.

Step 1 (System initialization): Given the security parameter \( S \), the bilinear parameters \( (q, G_1, G_2, e, P) \) are generated by the function \( setup(S) \). It is assumed that a unique \( ID \) is given to the health care provider (hcp) by a trusted authority and the health service providers will do the following initializations:

1) Select a random number \( \alpha \in R \mathbb{Z}_q^* \) and compute the public key \( PK_{hcp} = \alpha P \).
2) Generate the hash function \( H_1 : \{0, 1\} \rightarrow G_1^* \) and compute the key \( K_{hcp} = H_1(ID) \) for message encryption and decryption;
3) Generate the secure hash function \( H_2 : \{0, 1\}^\ast \rightarrow \{0, 1\}^\ast, H_3 : \{0, 1\}^\ast \rightarrow G_1^* \) and \( H_4 : G_2 \rightarrow \{0, 1\}^\ast \).
4) Compute the remote user’s pseudo-identity \( (UPID) = H_2(UID) \), and store a copy of it for future verification;
5) Securely distribute \( UPID, H_2, H_3, \) and \( H_4 \) to its subscribers.

An individual user (U) will do the following steps:

1) User Chooses a random number \( r \in R \mathbb{Z}_q^* \) and computes the public key \( PK_U = rP \).
2) User selects a random number $\beta \in R Z_n$, to calculate the session key $P = \beta P$.

3) User computes the message token $T = H_2(m[U_{PID}]_{session_id})$ and sends it to the receiver along with encrypted data and session key.

**Step 2 (Secure message communication):** After the system initialization, both parties use the data encryption and decryption algorithms to securely transmit their data. Here, we show how an user will encrypt the message ‘m’ (Equ.1) and decrypt the encrypted message by the corresponding eHealth care service provider. The user encrypts the message, $m$, based on the public key of the corresponding receiver using the identity based encryption [12].

$$v = Encrypt_1(PK_{ehp}, m, PK_U) = m \oplus H_4(g_U^v)$$  \hspace{1cm} (1)

Here, $Q_U = H_3(U_{PID})$; $H_3 : \{0,1\}^* \rightarrow G_1$, a random oracle; $g_U = e(Q_U, PK_{ehp})$, and $H_1 : G_2 \rightarrow \{0,1\}^*$, a random oracle.

The encrypted message is decrypted using the $Dec_{1}(PK_U, v, d)$ function, where $d = \alpha H_3(U_{PID})$ and $\alpha$ is the secret key of the corresponding agent.

$$Decrypt_1(PK_U, v, d) = m$$  \hspace{1cm} (2)

The eHealth service provider verifies the signature by using the equation (4).

$$e(vP + \beta P + PK_{UPDA} + TP, S) = e(P, P)$$  \hspace{1cm} (4)

**Step 3 (Message Signature and Verification):** To ensure data integrity, the receiver will verify the message signature after receiving it. By doing it, the eHealth service provider can verify the data originated from the specific patient and cannot be altered after signing it. We use the cryptographic digital signature (Equ.3), based on the bilinear pairing to provide data integrity. The patient first creates a session key $P = \beta P$, here $\beta \in R Z_n$, and computes the message token $T$. He then computes the signature using the equation (3).

$$S = \frac{1}{v + \beta + r + T}P$$  \hspace{1cm} (3)

The eHealth service provider verifies the signature by using the equation (4).

**Access Tree (T):** Let $T$ represent an access structure. Each non-leaf node of the tree represents a threshold gate. If $num_x$ is the number of children of a node $x$ and $k_x$ is the threshold value, then $0 \leq k_x \leq num_x$. When $k_x = 1$, the threshold gate is an OR gate, when $k_x = num_x$, it is an AND gate, finally when $1 \leq k_x \leq num_x$, it is a combination of AND and OR gates (Fig. 2). The function $parent(x)$ returns the parent of node $x$. The function $att(x)$ is defined only if $x$ is a leaf node and denotes the attribute associated with the leaf node $x$. The function $index(x)$ returns an ordering number associated with node $x$.

Let $T$ be an access tree with root ‘r’. Denote by $T_r$ the subtree of $T$ rooted at the node ‘x’. Hence $T_r$ is the same as $T_r$. If a set of health attributes $\omega$ satisfies the access tree $T_x$, we denote it as $T_x(\omega) = 1$. We compute $T_x(\omega)$ recursively as follows:

If ‘x’ is a non-leaf node, evaluate $T_x(\omega)$ for all children $z$ of node ‘x’. $T_x(\omega)$ returns 1 if and only if at least $k_x$ children return 1. If ‘x’ is a leaf node, $T_x(\omega)$ returns 1 if and only if $att(x) \in \omega$.

**Data formation and authentication:** Before encrypting the data packets, the trusted eHealth care provider classifies the data set based on some privacy levels and assigns some attributes on that message block (M). It then concatenates the message block (M), user pseudo identity $U_{PID}$, and the session id. After that the trusted eHealth care provider computes the token value $T = H_2(M[U_{PID}]_{session_id})$. It then computes the signature using the equation 3. Local health care provider will store the block sequence and patient pseudo identity for future verification. Fig. 4 shows the data packet structure. The health cloud service provider will check the message authenticity by verify the signature using the equation 4.

In a traditional public key cryptography system, the receiver and sender need each other public parameters to encrypt a message. But in the eHealth care system, the patient does not have any knowledge about the data requester or does not know who is going to access his PHI. Therefore, the security scheme by itself has to be capable to grant access control remotely. We use attribute based ciphertext policy with privacy leveling to solve this challenge. Based on the different roles of the data requesters, an access tree is created and the requester needs to provide corresponding attributes (nodes of the tree) to have the secret key and thereafter he can use the secret key to decrypt the encrypted data (PHI). Providing falls attributes will stop the decryption processes immediately and the data requester learns nothing more than the attributes he/she is entitled. Details construction of the access tree with related key-generation, encryption, and decryption algorithms are described below.

**Encrypt2(PK, M, T):** The algorithm first chooses a polynomial $q_x$ for each node $x$ in the tree $T$. These polynomials are chosen in a top-down manner, starting from the root node. For each node $x$ in the tree, set the degree $d_x$ of the polynomial $q_x$, to be one less than the threshold value of $k_x$. Starting with the root node ‘R’, the algorithm chooses a random $s \in Z_p$ and sets $q_R(0) = s$. Then it chooses $d_R$ other points of the polynomial $q_R$ randomly to define it completely. For any other node $x$, it sets $q_x(0) = q_{parent(x)}(index(x))$ and chooses $d_x$ other points randomly to completely define $q_x$. Finally, the ciphertext is then constructed by giving the
access tree structure $T$ and compute
\[ CT = (T, C) = Me(g, g)\alpha s, C = h^s, \]
\[\forall y \in Y : C_y = g^{y(0)}, C_y' = H(\text{att}(y))^{y(0)}\]
(5)

**KeyGen(MK,S):** The key generation algorithm takes as input a set of attributes $S$ and outputs a key that identifies with the set. The algorithm first chooses a random $r \in Z_p$, and then random $r_j \in Z_p$ for each attribute $j \in S$, and outputs the key as
\[ SK = (D = g^{\alpha+r}/\beta, \]
\[\forall j \in S : D_j = g^r.H(j)^{r_j}, D_j' = g^{r_j})\]
(6)

**Decrypt2**(CT, SK): The decryption procedure works as recursively and is defined by the function **DecryptNode** (CT, SK, x) that takes as input a ciphertext CT and a private key SK. If the node x is a leaf node, then the function works as follows:
\[ \text{DecryptNode}(CT, SK, x) = e(D, C_x) \]
\[= e(g^r.H(j)^{r_j})^{r(0)} = e(g, g)^{r(0)} \]
\[\text{Here } i \in S. \text{ If } i \notin S, \text{ we define} \]
\[\text{DecryptNode}(CT, SK, x) = \perp.\]

When x is a non-leaf node, the algorithm is called by all its child nodes z. It then stores the output of **DecryptNode** (CT, SK, z) as Fz. Detail is shown in [2]. If the data requester can submit all the attributes correctly, the algorithm then executes on the root node ‘R’. If the tree is satisfied by S, we set
\[ A = \text{DecryptNode}(CT, SK, r) = e(g^r, g)^{r(0)} = e(g, g)^{r}.\]
The message ‘M’ can be decrypted by computing
\[ C'/e(C, D)/A = C'/e(h^s, g^{(\alpha+r)/\beta})/e(g, g)^{rs} = M \]

**VI. SECURITY ANALYSIS**

In this section, we evaluate the security and privacy issues of the proposed scheme.

**The PEACE scheme ensures user and eHealth agent’s identity privacy:** User and health agent use pseudo identity instead of their unique identity, and these pseudo identities are generated by a strong one-way hash function. The construction of the hash function is easy to sample and compute but hard to invert. Therefore, the privacy is ensured by the proposed scheme.

**The scheme is secure to chosen ciphertext-only attack:**

Data transmissions from user to health agent, as well as from health agent to health cloud service provider are done with proper encryption schemes (Encryption1 and Encryption2). The processes are indistinguishable under chosen ciphertext attack based on the BDH problem hardness and this hardness ensures there is no probabilistic polynomial time algorithm that can decrypt the message from a set of chosen ciphertext.

**The scheme is resistant to the eavesdropping and collusion attacks:** An eavesdropping attacker aims at accessing the private and sensitive patient’s medical data. This attack may be happened during the patient to eHealth care provider or eHealth care provider to the health cloud data communication. The BDH hardness ensures that the proposed scheme is resistant to this eavesdropping attack. To access the data at the health cloud server, an attacker needs to have sufficient attributes to complete the access tree. Here the random number ‘s’ is divide into multiple shares based on the attributes set. For the non-privacy data set, he may get access and its allowed in our scheme. But he can’t modify the data due to the verification bindings. However, for the patient sensitive data, a unique random number is embedded into both ‘C’ and ‘D’ of the equation shown in the **Decrypt2**(CT, SK) function. Without knowing that secret number, it is impossible to access the data in a probabilistic polynomial time. This hardness also demonstrates our scheme as a resistant to the collusion attack. Therefore, any attacker cannot successfully launch the eavesdropping or collusion attack to our proposed scheme.

**The scheme ensures message integrity, non-repudiation, and source authentication:** We use the patient’s secret key and the session identity to generate the signature ‘S’ (Equ.3). The data receiver can verify the signature by using the public parameters of the sender, shown in the Equ. 4. This verification ensures the corresponding source authentication. The scheme generates the message token value ‘T’ by computing the hash value of the concatenated message, patient’s identity (PID), and a session sequence number. Only the patient and the eHealth care provider know the patient’s original identity and the session sequence number. This token value is also used to generate the signature ‘S’. Therefore, the message integrity with non-repudiation can be provided by our proposed scheme.

**VII. PERFORMANCE ANALYSIS**

In this section, we first show the timing cost of operations used in PEACE. We then analyze the performance of PEACE to resist DoS attack, and conduct a simulation using NS 2.33.

**Time cost:** We consider 20ms and 550ms as the computation time for the pairing using a personal computer and PDA respectively [13]. Time cost of PEACE operations is given in table I.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Time</th>
<th>Operation</th>
<th>Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Encryption1</td>
<td>$C_e$</td>
<td>Signature</td>
<td>$C_m$</td>
</tr>
<tr>
<td>Verification</td>
<td>$C_e$</td>
<td>Encryption1</td>
<td>$C_e$</td>
</tr>
<tr>
<td>Encryption2</td>
<td>$C_e + 2C_m$</td>
<td>Decryption2</td>
<td>$2C_e + C_m$</td>
</tr>
</tbody>
</table>

We denote by $C_e$ a computation of the pairing, and $C_m$ a scalar multiplication in $G_1$. Usually, pairing operations cost is much more than other computations. A single pairing $C_e$ needs about 10 times more time to compute than a scalar multiplication $C_m$ [14].

**Analysis:** The system blocking probability can be increased by high data rate traffic, or accessing the system by a large number of misbehaving users at a time. This increased rate of blocking probability is considered as a cause of DoS attack. In our analysis, we aim to minimize the blocking probability by restricting data rate and using multiple servers. We assume that the service provider serves multiple users. Users demand services according to a Poisson process and request independent and identical distributed exponential service time. We use $M/M/1/K$ and $M/M/m/K$ queuing model for analysis and assume that the blocking probability should be less than 30% to provide adequate Quality of Service (QoS) to the users. Blocking probability $P_b(K)$ and $P_m(K)$ of the $M/M/1/K$ and $M/M/m/K$ queue respectively can be written as follow:
Derivation of above equations can be found in [15]. We consider the arrival rates \( \lambda \) for the normal and high data rate traffic are 3 and 6 per unit of time, respectively, while the service rate \( \mu = 10 \) is fixed. The number of users, \( K \), varies from 0 to 50. For the M/M/m/K queue, the number of servers \( m = 2 \).

In this paper, we have proposed a scheme, PEACE, to achieve patient-centric access control with security and privacy by exploiting attribute based encryption. Moreover PEACE enables the eHealth care service provider to reduce the overall maintaining cost by moving data to a centralized storage or cloud storage for further processing and long-term storage. The proposed scheme also preserves user privacy with data integrity. Through detailed security and performance analyses, it has been demonstrated that the proposed scheme is highly efficient to resist various possible attacks and malicious behavior.
