Implementing Search

Assigned on: Friday, Oct 27, 2023
Due: Friday, Nov 10, 2023
Value: Bonus homework, 80 points.

The goal of the programming assignment is to give a chance to implement search, run experiments, and report your results. There are two options:

1. Romanian Holidays
2. The 3×3 sliding-tile puzzle

We provide detailed guidance on how to implement the first option. We provide significantly less guidance for the second option.

1. You can do either option. You will receive a grade for only one of the options, not both. If you do both, you must specify the one for which you want to be graded.

2. Programming assignment should be submitted with handin.

3. Do not hesitate to seek help during recitation and office hours.

Contents

1 Romanian Holidays (Total 80 points) 2
1.1 Data structures (38 points) 2
1.1.1 Tasks 2
1.2 Implementing Search (42 points) 3
1.2.1 Results to report 4
1.2.2 Some indications 4

2 Sliding-Tile Puzzle (80 points) 5
2.1 Requirements 5
2.2 Indications 6
1 Romanian Holidays (Total 80 points)

This exercise will guide you, step by step, to implement the data structures representing Romania’s map and the search algorithms for conducting search.

Note that in the following sections, we refer to variable and function names that may not be accepted by the programming language you choose (e.g., C, C++, and Java variables cannot contain hyphens). In these cases, just use names that are similar but acceptable by the language by, for example, using camel case instead of hyphens. Additionally, an association list is merely a list of key-value pairs.

It is not necessary to exactly implement these structures, but your implementation should be similar enough that the graders can clearly see the analogous variables and structures.

1.1 Data structures (38 points)

Create the data structures required to represent the map of Romania. Include the information about the distances between two cities linked by a road as well as the distance from any given city to Bucharest as indicated in Figure 1.

![Map of Romania with road distances in kilometers and straight-line distances to Bucharest.](image)

Figure 1: Map of Romania with road distances in kilometers and straight-line distances to Bucharest.

Indications (follow illustration in Figure 2):

- Create a data structure for a city.
- Include an attribute `name` to store the name of the city.
- Include an attribute `neighbors` to store the neighboring cities.
- Include an attribute `h` that provides the value of the straight-line distance to Bucharest.
- Create two ways to access the cities:
  1. a list called `allCitiesList` and
  2. a hash-table `allCitiesHash`
- After creating structures for all the cities, loop through them again in order to include, in the relevant attribute of a city, a reference its neighboring cities. Store these neighbors as an association list of the structure of a neighbor and the distance between the two.

1.1.1 Tasks

1. (8 points) Design, implement and test your map.

2. (4 points) Write a function `allCitiesFromList` that takes a global variable, `allCitiesList`, and returns a list of all names of cities on the map.
3. (4 points) Write a function `allCitiesFromHtable` that takes a variable, `allCitiesHtable` and returns a list of all the structures of cities on the map.

4. (4 points) Write two functions `getCityFromList` and `getCityFromHtable` that take the name of a city as input and return the corresponding structure (by accessing a variable, `allCitiesList` and `allCitiesHtable`, respectively).

5. (4 points) Write two functions `neighborsUsingList` and `neighborsUsingHtable` that take the name of a city as input and return the list of structures of its direct neighbors. `neighborsUsingList` and `neighborsUsingHtable` should use `getCityFromList` and `getCityFromHtable`, respectively.

6. (7 points) Using `allCitiesHtable`, write a function `neighborsWithinD` that takes the name of a city `myCity` and a number `distance`, then returns, for all direct neighbors within distance from `myCity` (≤), an association list of the structures of the neighbors of `myCity` and their distance to `myCity`.

7. (7 points) Using `allCitiesHtable`, write a function `neighborsP` that takes the name of two cities `cityOne` and `cityTwo`, and returns the distance between them if they are directly connected or nil if they are not.

1.2 Implementing Search (42 points)

You are asked to implement search the following search strategies, first as a Tree-Search then as a Graph-Search:

- (7 points) Any uninformed search strategy of your choice,
- (7 points) A Greedy search strategy, and
- (7 points) An A* search strategy.

for the ‘Romanian Holiday’ problem. Needless to say, you should first get Section 1 to work. Write `Search` that take as input the name of any city on the map, the name of a search strategy, and outputs:

1. The path to Bucharest,
2. The number of nodes generated/visited by the search process,
3. The cost of the path found (even when the function \( g(n) \) is not used to choose the node to expand),
4. The running time spent on the search.

Hints:
- You may choose to write one search function and give it the strategy as an argument.

1.2.1 Results to report
In addition to your code, report the results of your two functions applied to each city in Romania as indicated in the table below. Report six total tables:

1. (7 × 3 points) Three (one for each search strategy) result table for Tree-Search.
2. (7 × 3 points) Three (one for each search strategy) result table for Graph-Search.

<table>
<thead>
<tr>
<th>Uninformed search of your choice</th>
</tr>
</thead>
<tbody>
<tr>
<td>City name</td>
</tr>
<tr>
<td>-----------</td>
</tr>
<tr>
<td>Arad</td>
</tr>
<tr>
<td>Bucharest</td>
</tr>
<tr>
<td>:</td>
</tr>
<tr>
<td>Vaslui</td>
</tr>
<tr>
<td>Zerind</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Greedy Search</th>
</tr>
</thead>
<tbody>
<tr>
<td>City name</td>
</tr>
<tr>
<td>---------------</td>
</tr>
<tr>
<td>Arad</td>
</tr>
<tr>
<td>Bucharest</td>
</tr>
<tr>
<td>:</td>
</tr>
<tr>
<td>Vaslui</td>
</tr>
<tr>
<td>Zerind</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>A* Search</th>
</tr>
</thead>
<tbody>
<tr>
<td>City name</td>
</tr>
<tr>
<td>-----------</td>
</tr>
<tr>
<td>Arad</td>
</tr>
<tr>
<td>Bucharest</td>
</tr>
<tr>
<td>:</td>
</tr>
<tr>
<td>Vaslui</td>
</tr>
<tr>
<td>Zerind</td>
</tr>
</tbody>
</table>

1.2.2 Some indications
Follow the requirements below:

1. For Graph-Search, modify the data structure of a city that you implemented in Section 1.1 to add one more field `visited`, initialized to `Mil`. Use this attribute for loop control during search: when a city is visited, set this field to `T`.

2. Create a new data structure to represent a node in the search tree. The structure should have attributes that `point` to the structures of its parent (when applicable), its children (list), the city it represents. Other attributes may be necessary, such as path value at the node.

3. Implement a function `expand-node` that takes a node in the search tree and generates its children, which, for Graph-Search, should correspond to cities not `yet` visited. It needs to generate one node data-structure per child.
4. Implement a function `evaluate-node` that takes a node and a search strategy and returns the value of the node (e.g., $g(n)$, $h(n)$ or $f(n)$).

5. Implement a function that takes a fringe (i.e., a list of nodes to be expanded) and returns the node to expand. As a refinement, you can provide the name of the search strategy as an optional second argument (check `:key` in the list of arguments of a function).

6. If you separate the implementation search strategy from the evaluation functions cleverly enough, you may be able to use the same search function for all search strategies you implement.

7. Implement the search strategies iteratively, not recursively.

8. Declare a global variable `*nnv*` for storing the number of nodes visited. The search function should set up its value and the function `expand-node` should increment this value at every expansion (technically, every instantiation of a search-node structure).

9. Load the information about the cities from the file `all-cities.lisp` which is on the course website (it is also acceptable to hard-code this information if you don’t want to parse a lisp file).

2 Sliding-Tile Puzzle (80 points)

The goal is to implement A* search for solving the 3×3 sliding-tile puzzle with the two admissible heuristics, namely,

1. the displaced tile heuristics and
2. the Manhattan distance heuristics.

2.1 Requirements

1. (15 points) Implement a generator of random states, to be used to generate an initial and a goal state.

2. (2 × 8 points) Implement the two heuristics as functions that take a current state and a goal state and compute the value of the heuristic as the estimate of the distance between the two states.

3. (20 points) Implement A* that
   - takes as arguments an initial state, a goal state, and the name of a heuristic function and
   - returns the list of moves (i.e., actions) of the empty tile from the initial state to the goal state, the cost of the path found, and the CPU time.

4. Count the movement of each tile as utility cost.

5. (9 points) Generate 100 combinations of random initial and goal states (more if possible).

6. (2 × 10 points) Run A* with each heuristic on each combination initial and goal states, reporting the following:

<table>
<thead>
<tr>
<th>Instance</th>
<th>Displaced tile</th>
<th>Manhattan Distance</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>#NV</td>
<td>Path Cost</td>
</tr>
<tr>
<td>Combination 1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Combination 2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Combination 99</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Combination 100</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
2.2 Indications

In contrast to the previous problem, you do not need to generate a state space. Use to the extent possible the explanations and the mechanisms provided above for the Romanian Holidays and adapt them to your needs.

1. Implement a state as a 2 dimensional array.
2. Implement a generator of random states, to be used to generate an initial and a goal state.
3. Implement a function that takes as input a state and computes the value of the heuristic function (there are two of them).
4. Implement functions that correspond to the actions of moving the empty tile north, south, east and west (similar to the Farmer’s dilemma).
5. Implement functions that determine whether a move is legal or not (similar to the Farmer’s dilemma). A move north is not legal when the empty tile is in the first row.

Alert: The state space of this puzzle has two connected components. If the initial state and the goal state are chosen from a different component, the puzzle instance is not solvable. To test whether or not an instance is solvable, a simple test exists, see https://www.geeksforgeeks.org/check-instance-8-puzzle-solvable/.
