Quicksort

• Worst-case running time is in \Theta(n^2)
• Remarkably efficient: average running time is in \Theta(n\lg n) constants factors hidden in \Theta(n\lg n) quite small
• Sorts in place (no need for external storage)
```

```

                                                                     else return j
                                                                                 then exchange A[i] \leftrightarrow A[j]
```

Partition procedure: example

• First, selects x = A[p] as a pivot, around which to partition $A[p \dots r]$ • of $A[p \dots r]$ such that every element in $A[p \dots i] \leq x$ and

лету 23, 2

• Initially, the regions are empty (i = p - 1 and j = r + 1)

every element in $A[j \dots r] \leq x$

Partition procedure: example

• Then, i is incremented and j is decremented until $A[i] \ge x \ge A[j]$

 \bullet At this point, A[i] is too big and A[j] is too small to be in respective region

9

They should be swapped which allows us to continue extending the regions

• This continues until $i \geq j$, with $A[p \dots r]$ partitioned in

 $A[p\dots q]$ and $A[q+1\dots r]$, where no element of $A[q\dots q]$ is larger than no element of $A[q+1\dots r]$

В.А. Сропецъ

Worst-case partitioning

Partition produces 2 regions:

- (1) 1 element
- (2) (n-1) elements

Suppose this happens at every step (When does this happen?)

π

But, since partitioning costs $\Theta(n)$ and $T(1) = \Theta(1)$, we have

$$T(n) = T(n-1) + \Theta(n) = \sum_{k=1}^{n} \Theta(k) = \Theta(\sum_{k=1}^{n} k) = \Theta(n^2)$$

Worst-case of Quicksort is as bad as that of Insertion-sort And this happens in cases where Insertion-sort is linear :—

element, including: There are various methods that can be used to pick the pivot

- Use leftmost element as the pivot
- Use the "median-of-three" rule to pick the pivot
- Choose as partitioning: median(a[p], a[(p+r)/2], a[r])

6

- Partitioning unlikely to generate a "degenerate" partition.
- Use a random element as the pivot
- yields randomized-partition
- The average complexity does not depend on the distribution of input sequences

February 23, 2001

В А Сропеіту

Performance of Quicksort

Is partitioning balanced or unbalanced?

Depends on which elements are used for partitioning

If unbalanced, Quicksort runs asymptotically as slow as If balanced, Quicksort runs asymptotically as fast as Mergesort

Insertion-sort

10

1. Worst-case partitioning Runs in $\Theta(n^2)$

Best-case partitioning Runs in $\Theta(n \lg n)$

Average (Balanced) partitioning Runs in $\Theta(n \lg n)$

February 23, 2001

February 23, 2001 February 23, 2001 B. A. Choueiry 91 ĞΙ 9-to-1 proportional split depth $\log_{10/9} n = \Theta(\lg n)$ Balanced partitioning: Suppose Partition always produces Then levels have cost at most n, until recursion terminates at Every level has cost n, until reaching boundary condition at depth Proportional split: recurrence tree Average case much closer to best case than to worst case Average-case partitioning Look at recurrence tree.. T(n) = T(9n/10) + T(n/10) + n $replaced \Theta(n)$ by n $\Theta(n \lg n)$

February 23, 2001

B. A. Choueiry

Best-case partitioning

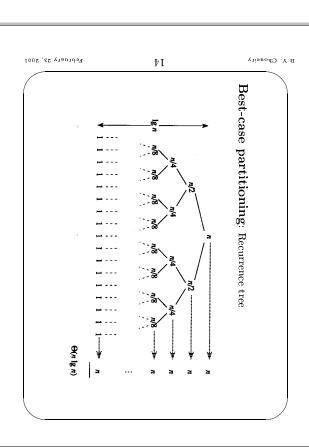

Partition produces two regions, each of size n/2

Recurrence is: $T(n) = 2T(n/2) + \Theta(n)$

13

Apply Case 2 of Master Theorem

Solution: $T(n) = \Theta(n \lg n)$

Performance of Quicksort

Courtesy of C. Cusack

level of recursion i may be different for each subarray, and at each n + (1-i)T + (i-n)T = (n)T: is noitized as forig

 $(n \operatorname{gol} n)\Theta = (n)T : \operatorname{noithlo} S$ Best case: $T(n) \le 2T(n/2) + n$.

Worst case:

 $(^{2}n)O = 2/(1+n)n =$ $1+\ldots+(1-n)+n \ =$ u + (1 - n)T = (n)T

 $T_{a}(n) = T + (1 - i) T_{a} T_{a}$ Average case:

February 23, 2001

Courtesy of C. Cusack

It can be shown that the solution is $T(n) = \Theta(n \lg n)$, whenever the split has constant proportionality

Thus, with 9-to-1 proportional split, quicksort runs is in $\Theta(n\lg n)$

Constant proportionality

Average Case

possible positions. This gives probability (1/n) to go into each of the n \bullet We assume that the pivot has the same

$$((i-n)_{n}T + (1-i)_{n}T) \sum_{1=i}^{n} \frac{1}{n} + n = (n)_{n}T$$

$$(i-n)_{n}T \sum_{1=i}^{n} \frac{1}{n} + (1-i)_{n}T \sum_{1=i}^{n} \frac{1}{n} + n = (n)_{n}T$$

$$(1-i)_n T \sum_{1=i}^n \frac{2}{n} + n =$$

- two sums are the same, but in reverse order. The last step comes from the fact that the
- $T(n) = O(n^2).$ $T(n) = O(n \log n)$ and in the worst case, \bullet We have seen that in the best case,
- positive constants a and b. • We guess that $T_a(n) \le an \log n + b$, for two
- \bullet We will prove this by induction.
