

ಲ

#### Context

- $\bullet\,$  In an MAS, agents affect each other's welfare
- Environment can be cooperative or competitive
- Competitive environments yield adverserial search problems (games)
- Approaches: mathematical game theory and AI games

Instructor's notes #9 March 30, 2005

B.Y. Choueiry

## Game theory vs. AI

- AI games: fully observable, deterministic environments, players alternate, utility values are equal (draw) or opposite (winner/loser)
  - In vocabulary of game theory: deterministic, turn-taking, two-player, zero-sum games of perfect information
- Games are attractive to AI: states simple to represent, agents restricted to a small number of actions, outcome defined by simple rules

Not croquet or ice hockey, but typically board games Exception: Soccer (Robocup www.robocup.org/)

4

B.Y. Choueiry

Board game playing: an appealing target of AI research

Board game: Chess (since early AI), Othello, Go, Backgammon, etc.

ರಾ

- Easy to represent
- Fairly small numbers of well-defined actions
- Environment fairly accessible
- Good abstraction of an enemy, w/o real-life (or war) risks :—)

But also: Bridge, ping-pong, etc.

Instructor's notes #9 March 30, 2005

B.Y. Choueiry

### Characteristics

- 'Unpredictable' opponent: contingency problem (interleaves search and execution)
- Not the usual type of 'uncertainty': no randomness/no missing information (such as in traffic) but, the moves of the opponent expectedly non benign

6

- Challenges:
  - huge branching factor
  - large solution space
  - Computing optimal solution is infeasible
  - Yet, decisions must be made. Forget A\*...

B.Y. Choueiry

7

### Discussion

• What are the theoretically best moves?

• Techniques for choosing a good move when time is tight  $\sqrt{\text{Pruning: ignore irrelevant portions of the search space}}$ × Evaluation function: approximate the true utility of a state

without doing search

Instructor's notes #9 March 30, 2005

# Two-person Games

- 2 player: Min and Max

- Max moves first

- Players alternate until end of game

- Gain awarded to player/penalty give to loser

#### Game as a search problem:

- Initial state: board position & indication whose turn it is
- Successor function: defining legal moves a player can take Returns {(move, state)\*}
- Terminal <u>test</u>: determining when game is over states satisfy the test: terminal states
- Utility function (a.k.a. payoff function): numerical value for outcome e.g., Chess: win=1, loss=-1, draw=0

B.Y. Choueiry

 $\infty$ 

#### Usual search

Max finds a sequence of operators yielding a terminal goal scoring winner according to the utility function

#### Game search

9

Min actions are significant
 Max must find a <u>strategy</u> to win regardless of what Min does:
 —> correct action for Max for each action of Min

Instructor's notes #9 March 30, 2005 • Need to approximate (no time to envisage all possibilities difficulty): a huge state space, an even more huge search space e.g., chess:  $\begin{cases} 10^{40} \text{ different legal positions} \\ \text{Average branching factor=35, 50 moves/player= } 35^{100} \end{cases}$ 

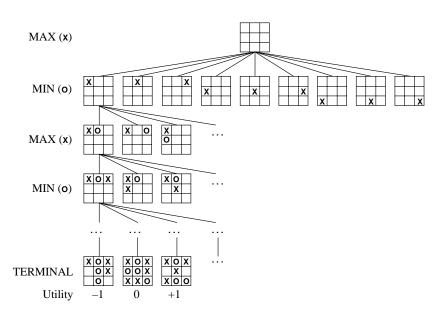

• Performance in terms of time is very important

B.Y. Choueiry

Example: Tic-Tac-Toe

Max has 9 alternative moves

Terminal states' utility: Max wins=1, Max loses = -1, Draw = 0

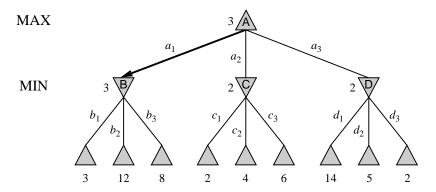

10

Example: 2-ply game tree

Max's actions:  $a_1$ ,  $a_2$ ,  $a_3$ Min's actions:  $b_1$ ,  $b_2$ ,  $b_3$ 

Minimax algorithm determines the optimal strategy for Max  $\rightarrow$  decides which is the best move

Instructor's notes #9
March 30, 2005

B.Y. Choueiry

12

## Minimax algorithm

- Generate the whole tree, down to the leaves
- Compute utility of each terminal state
- Iteratively, from the leaves up to the root, use utility of nodes at depth d to compute utility of nodes at depth (d-1):

MIN 'row': minimum of children MAX 'row': maximum of children

MINIMAX-VALUE (n)

Utility(n) if n is a terminal node  $max_{s \in Succ(n)}$  Minimax-Value(s) if n is a Max terminal node

 $min_{s \in Succ(n)}$ MINIMAX-VALUE(s) if n is a Min node

B.Y. Choueiry

13

### Minimax decision

- MAX's decision: <u>minimax decision</u> maximizes utility under the assumption that the opponent will play perfectly to his/her own advantage
- Minimax decision maximes the worst-case outcome for Max (which otherwise is guaranteed to do better)
- If opponent is sub-optimal, other strategies may reach better outcome better than the minimax decision

Instructor's notes #9 March 30, 2005

B.Y. Choueiry

14

# Minimax algorithm: Properties

• m maximum depth
b legal moves

• Using Depth-first search, space requirement is: O(bm): if generating all successors at once

O(m): if considering successors one at a time

• Time complexity  $O(b^m)$ 

Real games: time cost totally unacceptable

15

# Multiple players games

Utility(n) becomes a vector of the size of the number of players

For each node, the vector gives the utility of the state for each player

(1, 2, 6)

(7, 4, 1)

to move A

В

В

C

(5, 1, 1)

(5, 4, 5)

(1, 5, 2)

(1, 5, 2)

(7,7,1) (5,4,5)

Instructor's notes #9 March 30, 2005

B.Y. Choueiry

#### Alliance formation in multiple players games

How about alliances?

16

A and B in weak positions, but C in strong position
A and B make an alliance to attach C (rather than each other
→ Collaboration emerges from purely selfish behavior!

• Alliances can be done and undone (careful for social stigma!)

• When a two-player game is not zero-sum, players may end up automatically making alliances (for example when the terminal state maximizes utility of both players)

17

# Alpha-beta pruning

- Minimax requires computing all terminal nodes: unacceptable
- Do we really need to do compute utility of <u>all</u> terminal nodes? ... No, says John McCarthy in 1956:

It is possible to compute the correct minimax decision without looking at every node in the tree, and yet get the correct decision

• Use pruning (eliminating useless branches in a tree)

Instructor's notes #9 March 30, 2005

B.Y. Choueiry

18

# Example of Alpha-beta pruning
