Introduction

Algorithm Analysis CSE235

How can we say that one algorithm performs better than another?

Quantify the resources required to execute:

- Time
- Memory
- I/O
- circuits, power, etc

Time is not merely CPU clock cycles, we want to study algorithms independent or implementations, platforms, and hardware. We need an objective point of reference. For that, we measure time by "the number of operations as a function of an algorithm's input size."

Input Size

Algorithm Analysis CSE235 For a given problem, we characterize the input size, n, appropriately:

- Sorting The number of items to be sorted
- Graphs The number of vertices and/or edges
- Numerical The number of bits needed to represent a number

The choice of an input size greatly depends on the *elementary* operation; the most relevant or important operation of an algorithm.

- Comparisons
- Additions
- Multiplications

Orders of Growth

Algorithm Analysis CSE235

Small input sizes can usually be computed instantaneously, thus we are most interested in how an algorithm performs as $n \to \infty$.

Indeed, for small values of n, most such functions will be very similar in running time. Only for sufficiently large n do differences in running time become apparent. As $n\to\infty$ the differences become more and more stark.

Intractability

Algorithm Analysis

CSE235

Problems that we can solve (today) only with exponential or super-exponential time algorithms are said to be (likely) intractable. That is, though they may be solved in a reasonable amount of time for small n, for large n, there is (likely) no hope of efficient execution. It may take millions or billions of years.

Tractable problems are problems that have efficient (read: polynomial) algorithms to solve them. Polynomial order of magnitude usually means there exists a polynomial $p(n) = n^k$ for some constant k that always bounds the order of growth. More on asymptotics in the next slide set.

Intractable problems may need to be solved using approximation or randomized algorithms.

Worst, Best, and Average Case

Algorithm Analysis CSE235

Some algorithms perform differently on various inputs of similar size. It is sometimes helpful to consider the Worst-Case, Best-Case, and Average-Case efficiencies of algorithms. For example, say we want to search an array $\mathcal A$ of size n for a given value K.

- Worst-Case: $K \notin \mathcal{A}$ then we must search *every* item (n comparisons)
- \bullet Best-Case: K is the first item that we check, so only one comparison

Average-Case

Algorithm Analysis Since any worth-while algorithm will be used quite extensively, the average running-time is arguably the best measure of its performance (if the worst-case is not frequently encountered). For searching an array, and assuming that p is the probability of a successful search, we have:

$$C_{avg}(n) = \frac{p + 2p + \dots + ip + \dots np}{n} + n(1 - p)$$

$$= \frac{p}{n}(1 + 2 + \dots + i + \dots + n) + n(1 - p)$$

$$= \frac{p}{n}\frac{(n(n+1))}{2} + n(1 - p)$$

If p=1 (search succeeds), $C_{avg}(n)=\frac{n+1}{2}\approx .5n$. If p=0 (search fails), $C_{avg}(n)=n$. A more intuitive interpretation is that the algorithm must examine, on average, half of all elements in A.

Average-Case

Algorithm Analysis CSE235

Average-Case analysis of algorithms is important in a practical sense. Often, C_{avg} and C_{worst} have the same order of magnitude and thus, from a theoretical point of view, are no different from each other. Practical implementations, however, require a real-world examination.

Mathematical Analysis of Algorithms

Algorithm Analysis CSE235

After developing pseudo-code for an algorithm, we wish to analyze its efficiency as a function of the size of the input, n in terms of how many times the elementary operation is performed. Here is a general strategy:

- **①** Decide on a parameter(s) for the input, n.
- Identify the basic operation.
- Evaluate if the elementary operation depends only on n (otherwise evaluate best, worst, and average-case separately.
- Set up a summation corresponding to the number of elementary operations
- $\textbf{§ Simplify the equation to get as simple of a function } f(n) \\ \text{as possible.}$

Analysis Examples Example I

Algorithm Analysis

CSE235

Consider the following code.

Algorithm (UNIQUEELEMENTS)

```
INPUT : Integer array \mathcal A of size n OUTPUT : true if all elements a \in \mathcal A are distinct 1 FOR i=1,\dots,n-1 DO 2 FOR j=i+1,\dots,n DO 3 IF a_i=a_j THEN return false 5 END 6 END
```

Analysis Example Example I - Analysis

Algorithm Analysis

For this algorithm, what is

- The elementary operation?
- Input Size?
- Does the elementary operation depend only on n?

Analysis Example Example I - Analysis

Algorithm Analysis

For this algorithm, what is

- The elementary operation?
- Input Size?
- Does the elementary operation depend only on n?

The outer for-loop is run n-2 times. More formally, it contributes

$$\sum_{i=1}^{n-1}$$

Analysis Example

Example I - Analysis

Algorithm Analysis

The inner for-loop *depends* on the outer for-loop, so it contributes

$$\sum_{j=i+1}^{n}$$

Analysis Example

Example I - Analysis

Algorithm Analysis CSE235

The inner for-loop *depends* on the outer for-loop, so it contributes

$$\sum_{j=i+1}^{n}$$

We observe that the elementary operation is executed once in each iteration, thus we have

$$C_{worst}(n) = \sum_{i=1}^{n-1} \sum_{j=i+1}^{n} 1 = \frac{n(n-1)}{2}$$

Analysis Example Example II

Algorithm Analysis CSE235 The *parity* of a bit string determines whether or not the number of 1s appearing in it is even or odd. It is used as a simple form of error correction over communication networks.

Algorithm (PARITY)

```
INPUT : An integer n in binary (b[])
OUTPUT : 0 if the parity of n is even, 1 otherwise

1 parity \leftarrow 0

2 WHILE n > 0 DO

3 IF b[0] = 1 THEN
4 parity \leftarrow parity \leftarrow parity + 1 \mod 2

5 right-shift(n)

6 END

7 END

8 return parity
```

Analysis Example

Example II - Analysis

Algorithm Analysis

For this algorithm, what is

- The elementary operation?
- Input Size?
- ullet Does the elementary operation depend only on n?

Analysis Example Example II - Analysis

Algorithm Analysis CSE235

For this algorithm, what is

- The elementary operation?
- Input Size?
- Does the elementary operation depend only on *n*?

The while-loop will be executed as many times as there are 1-bits in its binary representation. In the worst case, we'll have a bit string of all ones.

Analysis Example Example II - Analysis

Algorithm Analysis CSE235

For this algorithm, what is

- The elementary operation?
- Input Size?
- Does the elementary operation depend only on n?

The while-loop will be executed as many times as there are 1-bits in its binary representation. In the worst case, we'll have a bit string of all ones.

The number of bits required to represent an integer n is

 $\lceil \log n \rceil$

so the running time is simply $\log n$.

Analysis Example Example III

Algorithm Analysis

CSE235

Algorithm (MYFUNCTION(n, m, p))

```
INPUT : Integers n,m,p such that n>m>p
OUTPUT : Some function f(n,m,p)

1 x=1

2 FOR i=0,\ldots,10 DO

3 FOR j=0,\ldots,n DO

4 FOR k=m/2,\ldots,m DO

5 x=x\times p

6 END

7 END

8 END

9 return x
```

Analysis Example Example III - Analysis

Algorithm Analysis

• Outer Loop: executed 11 times.

Analysis Example

Example III - Analysis

Algorithm Analysis

- Outer Loop: executed 11 times.
- 2nd Loop: executed n+1 times.

Analysis Example

Example III - Analysis

Algorithm Analysis

- Outer Loop: executed 11 times.
- 2nd Loop: executed n+1 times.
- Inner Loop: executed about $\frac{m}{2}$ times.

Analysis Example Example III - Analysis

Algorithm Analysis

CSE33

- Outer Loop: executed 11 times.
- 2nd Loop: executed n+1 times.
- Inner Loop: executed about $\frac{m}{2}$ times.
- Thus we have

$$C(n, m, p) = 11(n+1)(m/2)$$

Analysis Example Example III - Analysis

Algorithm Analysis

CSE23

- Outer Loop: executed 11 times.
- 2nd Loop: executed n+1 times.
- Inner Loop: executed about $\frac{m}{2}$ times.
- Thus we have

$$C(n, m, p) = 11(n+1)(m/2)$$

• But, do we really need to consider p?

Summation Tools I

Algorithm Analysis CSE235

Section 3.2 (p229) has more summation rules. You can always use Maple to evaluate and simplify complex expressions (but know how to do them by hand!).

To invoke maple, on cse you can use the command-line interface by typing maple. Under unix (gnome or KDE) or via any xwindows interface, you can use the graphical version via xmaple.

Will be demonstrated during recitation.

Summation Tools II

Algorithm Analysis

Example

> simplify(sum(i, i=0..n));

$$\frac{1}{2}n^2 + \frac{1}{2}n$$

> Sum(Sum(j, j=i..n), i=0..n);

$$\sum_{i=0}^{n} \left(\sum_{j=1}^{n} j \right)$$
