

ಲು

### Context

- In an MAS, agents affect each other's welfare
- Environment can be cooperative or competitive
- Competitive environments yield adverserial search problems (games)
- Approaches: mathematical game theory and AI games

Instructor's notes #9 March 31, 2008

### Game theory vs. AI

• AI games: fully observable, deterministic environments, players alternate, utility values are equal (draw) or opposite (winner/loser)

In vocabulary of game theory: deterministic, turn-taking, two-player, zero-sum games of perfect information

• Games are attractive to AI: states simple to represent, agents restricted to a small number of actions, outcome defined by simple rules

Not croquet or ice hockey, but typically board games Exception: Soccer (Robocup www.robocup.org/)

B.Y. Choueiry

4

B.Y. Choueiry

Board game playing: an appealing target of AI research

Board game: Chess (since early AI), Othello, Go, Backgammon, etc.

ರ

- Easy to represent
- Fairly small numbers of well-defined actions
- Environment fairly accessible
- Good abstraction of an enemy, w/o real-life (or war) risks :—)

But also: Bridge, ping-pong, etc.

Instructor's notes #9 March 31, 2008

B.Y. Choueiry

#### Characteristics

- 'Unpredictable' opponent: contingency problem (interleaves search and execution)
- Not the usual type of 'uncertainty': no randomness/no missing information (such as in traffic) but, the moves of the opponent expectedly non benign

6

- Challenges:
  - huge branching factor
  - large solution space
  - Computing optimal solution is infeasible
  - Yet, decisions must be made. Forget A\*...

B.Y. Choueiry

~1

### Discussion

• What are the theoretically best moves?

Techniques for choosing a good move when time is tight
 √ Pruning: ignore irrelevant portions of the search space
 × Evaluation function: approximate the true utility of a state
 without doing search

Instructor's notes #9 March 31, 2008

B.Y. Choueiry

### Two-person Games

- 2 player: Min and Max

- Max moves first

- Players alternate until end of game

- Gain awarded to player/penalty give to loser

 $\infty$ 

### Game as a search problem:

- Initial state: board position & indication whose turn it is
- Successor function: defining legal moves a player can take Returns {(move, state)\*}
- Terminal <u>test</u>: determining when game is over states satisfy the test: <u>terminal states</u>
- Utility function (a.k.a. payoff function): numerical value for outcome e.g., Chess: win=1, loss=-1, draw=0

### Usual search

Max finds a sequence of operators yielding a terminal goal scoring winner according to the utility function

#### Game search

9

Min actions are significant
 Max must find a <u>strategy</u> to win regardless of what Min does:
 —> correct action for Max for each action of Min

Instructor's notes #9 March 31, 2008 • Need to approximate (no time to envisage all possibilities difficulty): a huge state space, an even more huge search space e.g., chess:  $\begin{cases} 10^{40} \text{ different legal positions} \\ \text{Average branching factor=35, 50 moves/player= } 35^{100} \end{cases}$ 

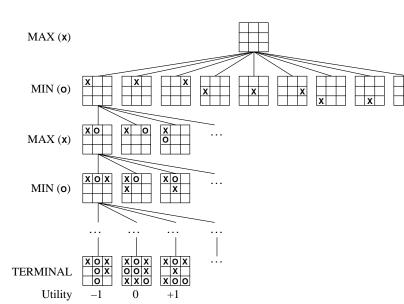

• Performance in terms of time is very important

B.Y. Choueiry

## Example: Tic-Tac-Toe

Max has 9 alternative moves

Terminal states' utility: Max wins=1, Max loses = -1, Draw = 0

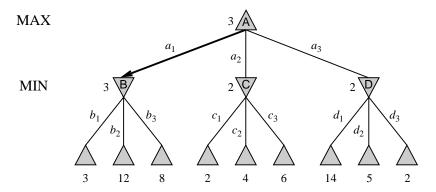

10

Example: 2-ply game tree

Max's actions:  $a_1$ ,  $a_2$ ,  $a_3$ Min's actions:  $b_1$ ,  $b_2$ ,  $b_3$ 

Minimax algorithm determines the optimal strategy for Max  $\rightarrow$  decides which is the best move

Instructor's notes #9 March 31, 2008

B.Y. Choueiry

12

### Minimax algorithm

- Generate the  $\underline{\text{whole}}$  tree, down to the leaves
- Compute utility of each terminal state
- Iteratively, from the leaves up to the root, use utility of nodes at depth d to compute utility of nodes at depth (d-1):

MIN 'row': minimum of children MAX 'row': maximum of children

MINIMAX-VALUE (n)

UTILITY(n) if n is a terminal node  $\max_{s \in Succ(n)} \text{MINIMAX-VALUE}(s)$  if n is a Max node  $\min_{s \in Succ(n)} \text{MINIMAX-VALUE}(s)$  if n is a Min node

B.Y. Choueiry

13

### Minimax decision

- MAX's decision: <u>minimax decision</u> maximizes utility under the assumption that the opponent will play perfectly to his/her own advantage
- Minimax decision maximes the worst-case outcome for Max (which otherwise is guaranteed to do better)
- If opponent is sub-optimal, other strategies may reach better outcome better than the minimax decision

Instructor's notes #9 March 31, 2008

B.Y. Choueiry

## Minimax algorithm: Properties

14

• m maximum depth
b legal moves

• Using Depth-first search, space requirement is: O(bm): if generating all successors at once

O(m): if considering successors one at a time

• Time complexity  $O(b^m)$ 

Real games: time cost totally unacceptable

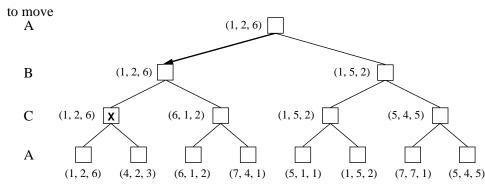

## Multiple players games

Utility(n) becomes a vector of the size of the number of players

For each node, the vector gives the utility of the state for each player

15

Instructor's notes #9 March 31, 2008

B.Y. Choueiry

### Alliance formation in multiple players games

How about alliances?

16

- A and B in weak positions, but C in strong position
  A and B make an alliance to attack C (rather than each other
  → Collaboration emerges from purely selfish behavior!
- Alliances can be done and undone (careful for social stigma!)
- When a two-player game is not zero-sum, players may end up automatically making alliances (for example when the terminal state maximizes utility of both players)

17

# Alpha-beta pruning

- Minimax requires computing all terminal nodes: unacceptable
- Do we really need to do compute utility of <u>all</u> terminal nodes? ... No, says John McCarthy in 1956:

It is possible to compute the correct minimax decision without looking at every node in the tree, and yet get the correct decision

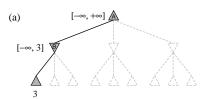

• Use pruning (eliminating useless branches in a tree)

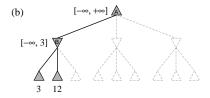

Instructor's notes #9 March 31, 2008

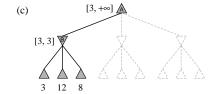

B.Y. Choueiry

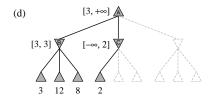

18

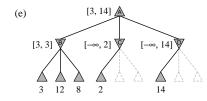

## Example of alpha-beta pruning

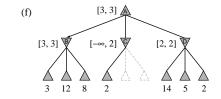

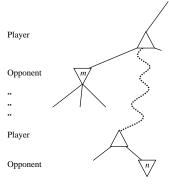

Try 14, 5, 2, 6 below D

# General principal of Alpha-beta pruning

If Player has a better choice m at  $\begin{cases} -\text{ a parent node of } n \\ -\text{ any choice point further up} \end{cases}$ n will never be reached in actual play

19

Instructor's notes #9 March 31, 2008

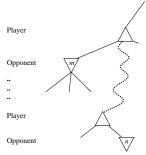

Once we have found enough about n (e.g., through one of it descendants), we can prune it (i.e., discard all its remaining descendants)

B.Y. Choueiry

## Mechanism of Alpha-beta pruning

 $\alpha$ : value of best choice so far for MAX, (maximum)

 $\beta$ : value of best choice so far for MIN, (minimum)

20

Alpha-beta search:

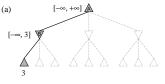

- updates the value of  $\alpha$ ,  $\beta$  as it goes along
- prunes a subtree as soon as its worse then current  $\alpha$  or  $\beta$

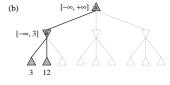

# Effectiveness of pruning

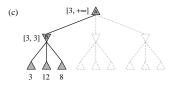

Effectiveness of pruning depends on the order of new nodes examined

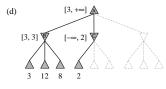

21

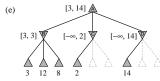

Instructor's notes #9 March 31, 2008

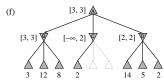

B.Y. Choueiry

### Savings in terms of cost

• Ideal case:

Alpha-beta examines  $O(b^{d/2})$  nodes (vs. Minimax:  $O(b^d)$ )

 $\rightarrow$  Effective branching factor  $\sqrt{b}$  (vs. Minimax: b)

22

• Successors ordered randomly: b > 1000, asymptotic complexity is  $O((b/\log b)^d)$ b reasonable, asymptotic complexity is  $O(b^{3d/4})$ 

Instructor's notes #9 March 31, 2008

 $\bullet$  Practically: Fairly simple heuristics work (fairly) well
