Berthe Y. Choueiry (Shu-we-ri) 402)472-5444

- Unification
- Inference mechanisms in First-Order Logic:
  - Forward chaining
  - Backward chaining
  - Resolution (and CNF)

N

### Universal instantiation (UI)

Every instantiation of a universally quantified sentence is entailed by it:

$$\frac{\forall v\alpha}{\text{Subst}(\{v/g\},\alpha)}$$

for any variable v and ground term g

E.g.,  $\forall x King(x) \land Greedy(x) \Rightarrow Evil(x)$  yields:

$$King(John) \wedge Greedy(John) \Rightarrow Evil(John)$$

 $King(Richard) \land Greedy(Richard) \Rightarrow Evil(Richard)$ 

 $King(Father(John)) \land Greedy(Father(John)) \Rightarrow Evil(Father(John))$ 

:

### Existential instantiation (EI)

For any sentence  $\alpha$ , variable v, and constant symbol kthat does not appear elsewhere in the knowledge base:

$$\frac{\exists v\alpha}{\operatorname{Subst}(\{v/k\},\alpha)}$$

E.g.,  $\exists x Crown(x) \land OnHead(x, John)$  yields

$$Crown(C_1) \wedge OnHead(C_1, John)$$

provided  $C_1$  is a new constant symbol, called a <u>Skolem constant</u>

Another example: from  $\exists x d(x^y)/dy = x^y$  we obtain

$$d(e^y)/dy = e^y$$

provided e is a new constant symbol

EI can be applied once to <u>replace</u> the existential sentence; the new KB is <u>not</u> equivalent to the old, but is satisfiable iff the old KB was satisfiable

CT

### Reduction to propositional inference (I)

 $\forall x King(x) \land Greedy(x) \Rightarrow Evil(x)$ 

King(John)

Greedy(John)

Brother(Richard, John)

Instantiating the universal sentence in all possible ways, we have:

 $King(John) \wedge Greedy(John) \Rightarrow Evil(John)$ 

 $King(Richard) \land Greedy(Richard) \Rightarrow Evil(Richard)$ 

King(John)

Greedy(John)

Brother(Richard, John)

The new KB is propositionalized: proposition symbols are:

King(John), Greedy(John), Evil(John), King(Richard) etc.

 $\neg 1$ 

#### Reduction to propositional inference (II)

- Claim: a ground sentence\* is entailed by new KB iff entailed by original KB
- Claim: every FOL KB can be propositionalized so as to preserve entailment
- Idea: propositionalize KB and query, apply resolution, return result
- Problem: with function symbols, there are infinitely many ground terms, e.g., Father(Father(Father(John)))

### Reduction to propositional inference (III)

- Theorem: Herbrand (1930). If a sentence  $\alpha$  is entailed by an FOL KB, it is entailed by a <u>finite</u> subset of the propositional KB
- Idea: For n=0 to  $\infty$  do create a propositional KB by instantiating with depth-n terms see if  $\alpha$  is entailed by this KB
- Problem: works if  $\alpha$  is entailed, loops if  $\alpha$  is not entailed
- Theorem: Turing (1936), Church (1936), entailment in FOL is semidecidable

### Problems with propositionalization

Propositionalization generates lots of irrelevant sentences.

E.g., from

 $\forall x King(x) \land Greedy(x) \Rightarrow Evil(x)$ 

King(John)

 $\forall y Greedy(y)$ 

Brother(Richard, John)

it seems obvious that Evil(John), but propositionalization produces lots of facts such as Greedy(Richard) that are irrelevant

With p k-ary predicates and n constants, there are  $p \cdot n^k$  instantiations!

#### Unification

We can get the inference immediately if we can find a substitution  $\theta$  such that King(x) and Greedy(x) match King(John) and Greedy(y)

 $\theta = \{x/John, y/John\}$  works

Unify $(\alpha, \beta) = \theta$  if  $\alpha\theta = \beta\theta$ 

p	q	heta	
Knows(John, x)	Knows(John,Jane)	$\{x/Jane\}$	
Knows(John,x)	Knows(y,OJ)	$\{x/OJ, y/John\}$	
Knows(John,x)	Knows(y, Mother(y))	$\{y/John,x/Mother(John)\}$	$i)\}$
Knows(John,x)	Knows(x,OJ)	fail	

Standardizing apart eliminates overlap of variables, e.g.,  $Knows(z_{17}, OJ)$ 

$$\frac{p_1', p_2', \dots, p_n', (p_1 \land p_2 \land \dots \land p_n \Rightarrow q)}{q\theta} \quad \text{where } p_i'\theta = p_i\theta \text{ for all } i$$

 $p_1'$  is King(John)  $p_1$  is King(x)  $p_2'$  is Greedy(y)  $p_2$  is Greedy(x)  $\theta$  is  $\{x/John, y/John\}$  q is Evil(x)  $q\theta$  is Evil(John)

GMP used with KB of <u>definite clauses</u> (<u>exactly</u> one positive literal) All variables assumed universally quantified

Instructor's notes #14April 13, 2015

#### Example knowledge base

The law says that it is a crime for an American to sell weapons to hostile nations. The country Nono, an enemy of America, has some missiles, and all of its missiles were sold to it by Colonel West, who is American.

Prove that Col. West is a criminal

... it is a crime for an American to sell weapons to hostile nations:  $American(x) \wedge Weapon(y) \wedge Sells(x,y,z) \wedge Hostile(z) \Rightarrow$  Criminal(x)

### Example of KB (2)

Nono . . . has some missiles, i.e.,  $\exists x \ Owns(Nono, x) \land Missile(x)$ :  $Owns(Nono, M_1)$  and  $Missile(M_1)$ 

... all of its missiles were sold to it by Colonel West  $\forall xMissile(x) \land Owns(Nono, x) \Rightarrow Sells(West, x, Nono)$ 

Missiles are weapons:

 $Missile(x) \Rightarrow Weapon(x)$ 

14

### Example of KB (3)

An enemy of America counts as "hostile":

 $Enemy(x, America) \Rightarrow Hostile(x)$ 

West, who is American ...

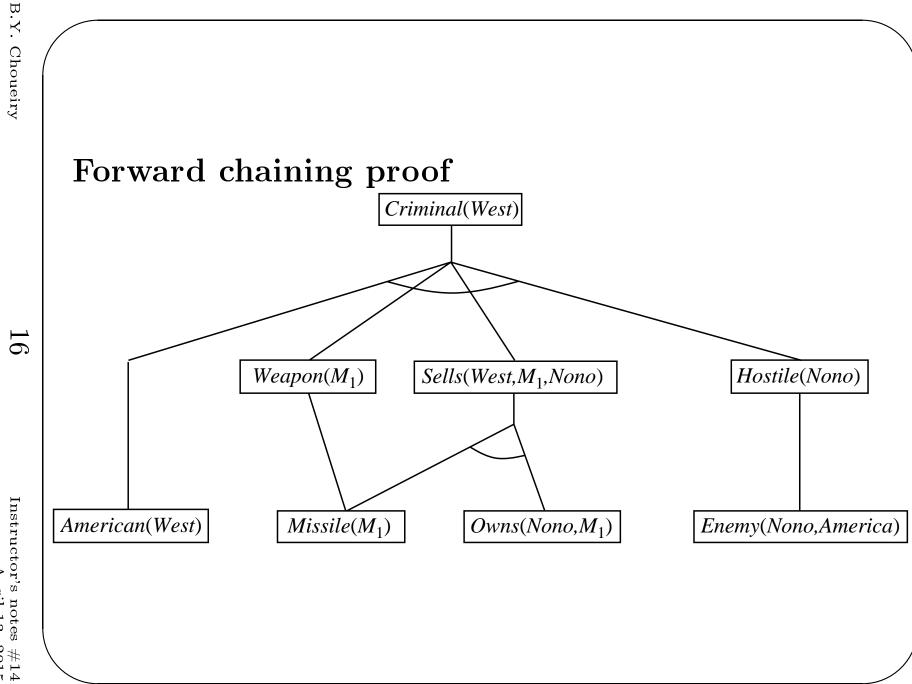

American(West)

The country Nono, an enemy of America ...

Enemy(Nono, America)

# Forward chaining algorithm

<FOL-FC-Ask, Figure 9.3 page 332>

## Properties of forward chaining

- Sound and complete for first-order definite clauses (proof similar to propositional proof)
- $\underline{\text{Datalog}} = \text{first-order definite clauses} + \underline{no\ functions}$  (e.g., crime KB)

  FC terminates for Datalog in poly iterations: at most  $p \cdot n^k$  literals
- May not terminate in general if  $\alpha$  is not entailed
- This is unavoidable: entailment with definite clauses is semidecidable

### Efficiency of forward chaining

- Simple observation: no need to match a rule on iteration k if a premise wasn't added on iteration k-1  $\Rightarrow$  match each rule whose premise contains a newly added literal
- Matching itself can be expensive
- Database indexing allows O(1) retrieval of known facts l e.g., query Missile(x) retrieves  $Missile(M_1)$
- Matching conjunctive premises against known facts is NP-hard
- Forward chaining is widely used in <u>deductive databases</u>

# Backward chaining algorithm

<FOL-BC-Ask, Figure 9.6 page 338>

Instructor's notes April 13, 8 #14 2015

### Properties of backward chaining

- Depth-first recursive proof search: space is linear in size of proof
- Incomplete due to infinite loops
  ⇒ fix by checking current goal against every goal on stack
- Inefficient due to repeated subgoals (both success and failure)

  ⇒ fix using caching of previous results (extra space!)
- Widely used (without improvements!) for logic programming

Resolution: brief summary

Full first-order version:

$$\frac{l_1 \vee \cdots \vee l_k, \quad m_1 \vee \cdots \vee m_n}{(l_1 \vee \cdots \vee l_{i-1} \vee l_{i+1} \vee \cdots \vee l_k \vee m_1 \vee \cdots \vee m_{j-1} \vee m_{j+1} \vee \cdots \vee m_n)\theta}$$

where Unify $(l_i, \neg m_j) = \theta$ .

For example,

$$\frac{\neg Rich(x) \lor Unhappy(x) \qquad Rich(Ken)}{Unhappy(Ken)}$$

with  $\theta = \{x/Ken\}$ 

Apply resolution steps to  $CNF(KB \wedge \neg \alpha)$ ; complete for FOL

23

### Conversion to CNF (I)

Everyone who loves all animals is loved by someone:

$$\forall x [\forall y Animal(y) \Rightarrow Loves(x, y)] \Rightarrow [\exists y Loves(y, x)]$$

1. Eliminate biconditionals and implications

$$\forall x [\neg \forall y \neg Animal(y) \lor Loves(x,y)] \lor [\exists y Loves(y,x)]$$

2. Move  $\neg$  inwards:  $\neg \forall x, p \equiv \exists x \neg p, \neg \exists x, p \equiv \forall x \neg p$ :

$$\forall x [\exists y \neg (\neg Animal(y) \lor Loves(x,y))] \lor [\exists y Loves(y,x)]$$

$$\forall x [\exists y \neg \neg Animal(y) \land \neg Loves(x,y)] \lor [\exists y Loves(y,x)]$$

$$\forall x [\exists y Animal(y) \land \neg Loves(x,y)] \lor [\exists y Loves(y,x)]$$

#### Conversion to CNF (II)

3. Standardize variables: each quantifier should use a different one

$$\forall x [\exists y Animal(y) \land \neg Loves(x,y)] \lor [\exists z Loves(z,x)]$$

4. Skolemize: a more general form of existential instantiation. Each existential variable is replaced by a <u>Skolem function</u> of the enclosing universally quantified variables:

$$\forall x [Animal(F(x)) \land \neg Loves(x, F(x))] \lor Loves(G(x), x)$$

5. Drop universal quantifiers:

$$[Animal(F(x)) \land \neg Loves(x, F(x))] \lor Loves(G(x), x)$$

6. Distribute  $\land$  over  $\lor$ :

$$[Animal(F(x)) \lor Loves(G(x), x)] \land [\neg Loves(x, F(x)) \lor Loves(G(x), x)]$$

# Resolution proof: definite clauses
