CSCE 230J Computer Organization

#### Linking

Dr. Steve Goddard goddard@cse.unl.edu

http://cse.unl.edu/~goddard/Courses/CSCE230J

#### Giving credit where credit is due

- Most of slides for this lecture are based on slides created by Drs. Bryant and O'Hallaron, Carnegie Mellon University.
- I have modified them and added new slides.

2

#### **Topics**

- ■Static linking
- **■**Object files
- ■Static libraries
- ■Loading
- ■Dynamic linking of shared libraries

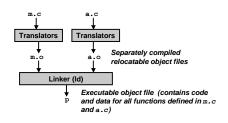

A Simplistic Program Translation Scheme

#### Problems

- Efficiency: small change requires complete recompilation
   Modularity: hard to share common functions (e.g. printf)
- Solution:
- Static linker (or linker)

A Better Scheme Using a Linker

Translating the Example Program

Compiler driver coordinates all steps in the translation and linking process.

- Typically included with each compilation system (e.g., gcc)
- Invokes preprocessor (cpp), compiler (cc1), assembler (as), and linker (1d).
- Passes command line arguments to appropriate phases

Example: create executable p from m.c and a.c:

bass> gcc -02 -v -o p m.c a.c
cpp [args] m.c /tmp/cca07630.i
ccl /tmp/cca07630.i m.c -o2 [args] -o /tmp/cca07630.s
as [args] -o /tmp/cca076301.o /tmp/cca07630.s
<similar process for a.c>
ld -o p [system obj files] /tmp/cca076301.o /tmp/cca076302.o
bass>

Page 1

#### What Does a Linker Do?

#### Merges object files

Merges multiple relocatable (.o) object files into a single executable object file that can be loaded and executed by the loader.

#### Resolves external references

- As part of the merging process, resolves external references.
  - External reference: reference to a symbol defined in another object file.

#### Relocates symbols

- Relocates symbols from their relative locations in the .o files to new absolute positions in the executable.
- Updates all references to these symbols to reflect their new positions.
  - References can be in either code or data

7

#### Why Linkers?

#### Modularity

- Program can be written as a collection of smaller source files, rather than one monolithic mass.
- Can build libraries of common functions (more on this later)
  - e.g., Math library, standard C library

#### Efficiency

- Time:
  - Change one source file, compile, and then relink.
- No need to recompile other source files.
- Space:
  - Libraries of common functions can be aggregated into a single file...
  - Yet executable files and running memory images contain only code for the functions they actually use.

8

### **Executable and Linkable Format** (ELF)

Standard binary format for object files

Derives from AT&T System V Unix

■ Later adopted by BSD Unix variants and Linux

#### One unified format for

- Relocatable object files (.o),
- Executable object files
- Shared object files (.so)

Generic name: FI F binaries

Better support for shared libraries than old a . out formats.

**ELF Object File Format** 

#### Flf heade

 Magic number, type (.o, exec, .so), machine, byte ordering, etc.

#### Program header table

- Page size, virtual addresses memory segments (sections), segment sizes.
- .text section
  - Code
- .data section
  - Initialized (static) data

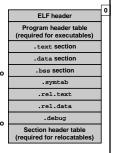

#### bss section

- Uninitialized (static) data
- "Block Started by Symbol"
- "Better Save Space"
- Has section header but occupies no space

ELF header
Program header table
(required for executables)
.text section
.data section
.bss section
.symtab
.rel.txt
.rel.data
.debug
Section header table
(required for relocatables)

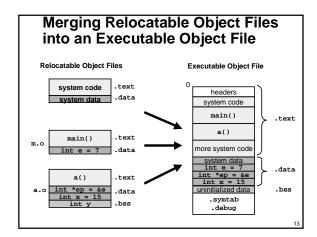

#### **ELF Object File Format (cont)**

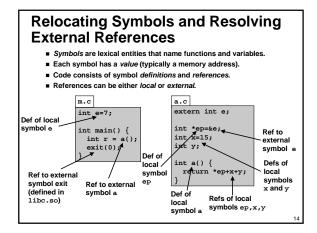

- .symtab section
  - Symbol table
  - Procedure and static variable names
- Section names and locations
- .rel.text section
  - Relocation info for .text section
  - Addresses of instructions that will need to be modified in the executable
  - Instructions for modifying.
- .rel.data section
  - Relocation info for .data section
  - Addresses of pointer data that will need to be modified in the merged executable
- .debug section
  - Info for symbolic debugging (gcc -g)

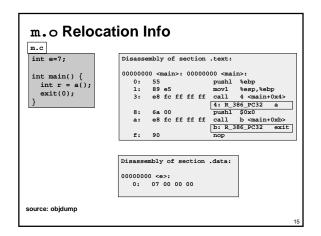

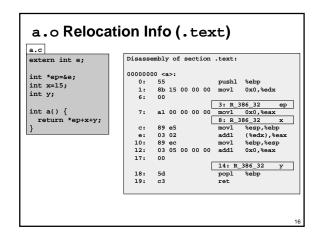

m.c
int e=7;
int main() {
 int r = a();
 exit(0);
}

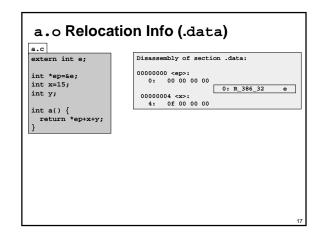

a.c
extern int e;
int \*ep=&e;
int x=15;
int y;
int a() {
 return \*ep+x+y;
}

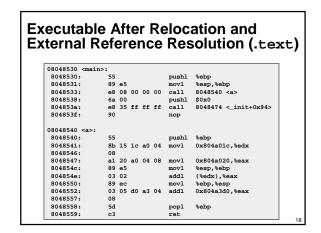

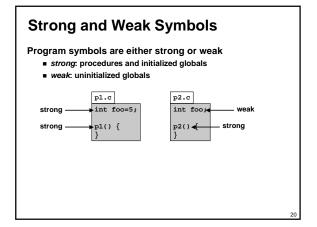

#### **Executable After Relocation and** External Reference Resolution(.data) int e=7; Disassembly of section .data: int main() { int r = a(); 0804a018 <e>: 804a018: 07 00 00 00 exit(0); 0804a01c <ep>: 18 a0 04 08 804a01c: a.c 0804a020 <x>: extern int e; 804a020: Of 00 00 00 int x=15; int y; int a() { return \*ep+x+y;

#### **Linker's Symbol Rules**

Rule 1. A strong symbol can only appear once.

Rule 2. A weak symbol can be overridden by a strong symbol of the same name.

■ references to the weak symbol resolve to the strong symbol.

Rule 3. If there are multiple weak symbols, the linker can pick an arbitrary one.

**Linker Puzzles** 

## Packaging Commonly Used Functions

How to package functions commonly used by programmers?

■ Math, I/O, memory management, string manipulation, etc.

Awkward, given the linker framework so far:

- Option 1: Put all functions in a single source file
  - Programmers link big object file into their programs
  - Space and time inefficient
- Option 2: Put each function in a separate source file
  - Programmers explicitly link appropriate binaries into their programs
  - More efficient, but burdensome on the programmer

Solution: static libraries (.a archive files)

- Concatenate related relocatable object files into a single file with an index (called an archive).
- Enhance linker so that it tries to resolve unresolved external references by looking for the symbols in one or more archives.
- If an archive member file resolves reference, link into executable.

Static Libraries (archives)

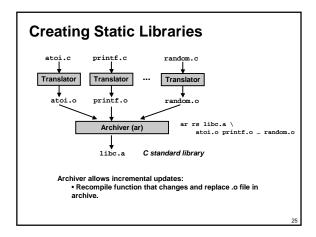

pl.o p2.o libc.a static library (archive) of relocatable object files concatenated into one file.

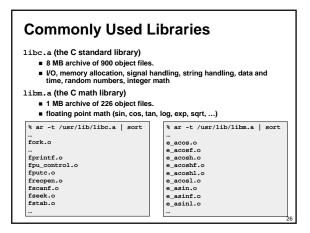

Linker (Id) executable object file (only contains code and data for libc functions that are called from pl.c and p2.c)

Further improves modularity and efficiency by packaging commonly used functions [e.g., C standard library (libc), math library (libm)]

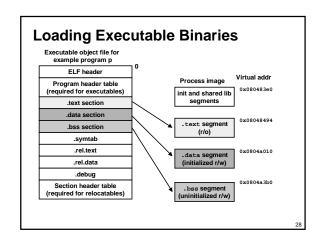

Linker selectively only the .o files in the archive that are actually needed by the program.

23

## Using Static Libraries Linker's algorithm for resolving external references: Scan. o files and a files in the command line order. During the scan, keep a list of the current unresolved references. As each new .o or .a file obj is encountered, try to resolve each unresolved reference in the list against the symbols in obj. If any entries in the unresolved list at end of scan, then error. Problem: Command line order matters! Moral: put libraries at the end of the command line. | bass | gcc | L. | libtest.o | libraries | | libtest.o. In function | main': | | libtest.o. (Lext+0x4): undefined reference to `libfun'

# Shared Libraries Static libraries have the following disadvantages: Potential for duplicating lots of common code in the executable files on a filesystem. • e.g., every C program needs the standard C library Potential for duplicating lots of code in the virtual memory space of many processes. • Minor bug fixes of system libraries require each application to explicitly relink Solution: • Shared libraries (dynamic link libraries, DLLs) whose members are dynamically loaded into memory and linked into an application at run-time. • Dynamic linking can occur when executable is first loaded and run. » Common case for Linux, handled automatically by 1d-1inux.so. • Dynamic linking can also occur after program has begun. » In Linux, this is done explicitly by user with dlopen(). » Basis for High-Performance Web Servers. • Shared library routines can be shared by multiple processes.
