

Declaring and Initializing String Variables

• Strings are character arrays

```
• Declaration is the same, just use char
  char string_var[100];
  char myName[30];
```

- myName will hold strings anywhere from 0 to 29 characters long
- Individual characters can be accessed/set using indices

```
myName[0] = 'B';
  myName[1] = 'r';
3
  myName[2] = 'i';
  myName[3] = 'a';
  myName[4] = 'n';
  printf("First initial: %c.\n", myName[0]);
```

Nebraska

Declaring and Initializing String Variables

- You can declare and initialize in one line
- Be sure to use the double quotes
- o char myName[30] = "Brian";
- You need not specify the size of the array when declaring-initializing in one line:
- char myName[] = "Brian";
- C will create a character array large enough to hold the string

4 D > 4 D > 4 E > 4 E > E 994 P

Null Terminating Character

Nebraska

- C needs a way to tell where the end of a string is
- With arrays, it is your responsibility to ensure you do not access memory outside the array
- To determine where the string ends, C uses the null-terminating character: '\0'
- Character with ASCII code 0

Null Terminating Character

char str[20] = "Initial value"; will produce the following in memory:

[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]
I	n	i	t	i	a	1		v	a
[10]	[11]	[12]	[13]	[14]	[15]	[16]	[17]	[18]	[19]

Nebraska

Arrays of Strings

- Without the null terminating character, C would not know where the string ends
- Many functions parse a string until it sees '\0'
- Without it, the program would run into memory space that doesn't belong to it
- char str[20] can only hold 19 characters: at least one character is reserved for '\0
- In declarations, char myName[] = "Brian", C automatically inserts the null-terminating character

40 × 40 × 42 × 42 × 2 990

Nebraska

Printing Strings

- You can use printf to print strings
- Use %s as a placeholder: printf("My Name is $%s.\n"$, myName);
- printf prints the string until the first null-terminating character
- Can specify minimum field width, as with e.g. int: printf("My Name is %20s.\n", myName);
- A negative field width will left justify instead of right justify

Arrays of Strings

CSCE150.

Introduction Basics

String Library
Substrings
Line Scanning
Sorting
Command
Line

• One string is an array of characters; an array of strings is a two-dimensional array of characters

```
#define NUM_PEOPLE 30
#define NAME_LEN 25
...
char names[NUM_PEOPLE][NAME_LEN];
```

• names can hold 30 names, each of up to 24 characters long

4 D > 4 D > 4 E > 4 E > E 900

Nebraska

Arrays of Strings

CSCE150

We can initialize an array of strings at declaration in the following manner:

```
char month[12][10] = {"January", "February",

"March", "April", "May", "June", "July",

"August", "September", "October",

"November", "December"};
```

- As with other arrays, the [12] is optional
- Why [10]?
- September is the longest string with 9 characters
- Needs an additional character for the null-terminating character

+ = > + = > + = > + = > + 9 < 0 <

Reading Strings I

CSCE1504

Nebraska

Introduction

String Library
Substrings
Line Scanning
Sorting
Command
Line

- You can use scanf and %s to read strings
- printf("Enter Topic: "); scanf("%s", string_var);
 - scanf skips leading whitespace characters such as blanks, newlines, and tabs
 - Starting with the first non-whitespace character, scanf copies the characters it encounters into successive memory cells of its character array argument
 - When a whitespace character is reached, scanning stops, and scanf places the null character at the end of the string in its array argument

Reading Strings II

CSCE150

ntroduction

ing Library bstrings

Line Scanning
Sorting
Command
Line
Arguments

- Note: no & is used
- The array is already represented by a memory address
- Dangerous: the user can put as many characters as they want
- If they input more characters than the string can hold: overflow
- Segmentation fault (if you're lucky), or may not even crash
- \bullet Rest of the program may produce garbage results

Nebraska

String Library Functions: Assignment and Substrings

CSCE150A

Introduction Basics

Copying
Concatenation
Comparisons
Length
Substrings

Substrings
Line Scanning
Sorting
Command
Line
Arguments

- \bullet The assignment operator, = works for simple data types
- For strings, = *only* works in the declaration

```
1 char message[30];
2 message = "Hello!"; ← |||legal
```

- This is because arrays point to a memory location
- Cannot assign arbitrary values to memory pointers
- Must use library functions to do so

Nebraska

String Library

CSCE150

Introduction Basics

String Library

Concatenation Comparisons Length Substrings Line Scanning

Line Scanning Sorting Command Line Arguments

- \bullet C provides a standard string library
- Use #include<string.h>
- \bullet Table 9.1 summarizes which functions are provided
- Copy, concatenation, comparison, length, tokenizer, etc.

10110101010

4 m > 4 m > 4 2 > 4 2 > 4 2 > **2** 4 9 9 9 9

String Assignment I

- To assign a value to a string, we actually copy it
- char *strcpy(char *dest, const char *src) copies string src (source) into dest (destination)
- Note:
 - Second argument has the keyword const: guarantees the source string is not modified
 - First argument must point to a memory location large enough to handle the size of dest
 - This is your responsibility; C does not do it for you
 - Returns a pointer to the first character of dest

4 D > 4 B > 4 B > 4 B > 3 8 9 9 9

Nebraska

String Assignment II

1 | char myEmail[30]; strcpy(myEmail, "bgriffin@cse.unl.edu");

• Be very careful:

```
char myEmail[10];
strcpy(myEmail, "bgriffin@cse.unl.edu");
```

• In this case, se.unl.edu would overwrite adjacent memory cells

+ = > + = > + = > + = > + 9 < 0 <

Nebraska

String Assignment I

CSCE150A

- C provides another copying function called strncpy: char *strncpy(char *dest, const char *src, size_t n);
- size_t is an unsigned integer (no negative value)
- Copies (up to) n character values of src to dest
- \bullet Actually copies n bytes, but 1 char is one byte

```
char myEmail[] = "bgriffin@cse.unl.edu";
2 char myLogin[30];
3
  //copy first 8 characters:
  strncpy(myLogin, myEmail, 8);
```

4D > 4B > 4B > 4B > B 990

Nebraska

String Assignment II

CSCE150A

ullet Pitfall: If there is no null-terminating character in the first n bytes of ${\tt src},\,{\tt strncpy}$ will not insert one for you

• You must add the null terminating character yourself

```
1 | char myEmail[] = "bgriffin@cse.unl.edu";
  char myLogin[30];
3 //copy first 8 characters:
4 strncpy(myLogin, myEmail, 8);
  myLogin[8] = '\0';
```

Nebraska

String Assignment III

- ullet If n is larger than ${
 m src}$, the null-terminating character is copied multiple times:
 - strncpy(aString, "Test", 8);
- Four null terminating characters will be copied
- Thus, aString contains "Test\0\0\0\0"

Nebraska

Concatenation I

- Concatenation is the operation of appending two strings
- C provides concatenation functions: char *strcat(char *dest, const char *src); char *strncat(char *dest, const char *src, size_t n);
- Both append src onto the end of dest

4 D > 4 B > 4 B > 4 B > 9 Q C

```
Nebraska
       Concatenation II
             char fullName[80];
              char firstName[30] = "Brian";
           2
              char lastName[30] = "Griffin";
           3
              strcpy(fullName,lastName);
           5
             strcat(fullName,", ");
           6
              strcat(fullName,firstName);
              printf("My name is %s\n", fullName);
          • Result: My name is Griffin, Brian
```

Nebraska Concatenation III \bullet strncat copies at most n bytes • From the documentation (man pages): If src contains n or more characters, strncat() writes n+1 characters to dest (n from src plus the terminating null byte). Therefore, the size of dest must be at least the length of dest+n+14 D > 4 D > 4 E > 4 E > E 994 P

Nebraska

Comparisons I

CSCE150A

• We can do character comparisons, 'A' < 'a'

- We can also do string comparisons (lexicographic order), but not with the usual operators <, > <=, etc.
- Strings (arrays of characters) are memory addresses
- string_1 < string_2 would compare the memory locations

4D> 4@> 4E> 4E> E 990

4 D > 4 B > 4 B > 4 B > B 9900

Nebraska

Comparisons II

• String library provides several comparison functions: int strcmp(const char *s1, const char *s2);

int strncmp(const char *s1, const char *s2, size_t n); • Both compare s1, s2

- - ullet If s1 < s2, returns a *negative* integer
 - If s1 > s2, returns a positive integer
 - If s1 == s2 returns zero

ullet strncmp compares only the first n characters

Nebraska

Comparisons III

```
char nameA[] = "Alpha";
   char nameB[] = "Beta";
3
   char nameC[] = "Alphie";
   char nameD[] = "BetaFish";
  if(strcmp(nameA, nameB) < 0)</pre>
    printf("%s comes before %s\n", nameA, nameB);
   if(strncmp(nameA, nameC, 4) == 0)
8
    printf("Almost the same!\n");
9
   if(strcmp(nameB, nameD) < 0)</pre>
10
    printf("%s comes before %s\n", nameB, nameD);
```

Nebraska

String Length

• The string library also provides a function to count the number of characters in a string: size_t strlen(const char *s);

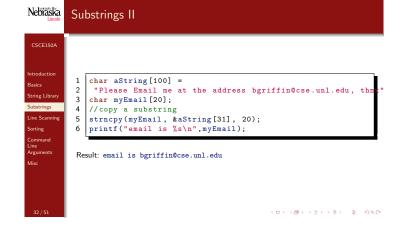

- Returns the number of characters (bytes) appearing before the null terminating character
- Does not count the size of the array!

```
char message[50] = "You have mail";
  int n = strlen(message);
  printf("message has %d characters\n",n);
3
```

Result: message has 13 characters

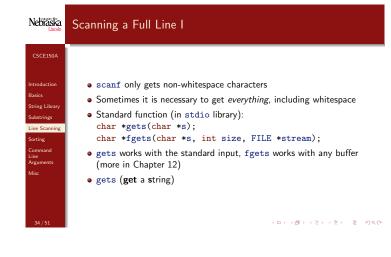

4 D > 4 B > 4 B > 4 B > 9 Q C

Substrings I CSCE150A A substring is a portion of a string, not necessarily from the beginning strincpy can be used to extract a substring (of n characters), but only from the beginning However, we can use referencing to get the memory address of a character Command Line Arguments Misc We can exploit this fact to copy an arbitrary substring

Pitfalls & Strategies CSCE150A Two most important questions when dealing with strings: String Library Substrings Line Scanning Sorting Ocommand Line Arguments Misc Pitfalls & Strategies Two most important questions when dealing with strings: Is there enough room to perform the given operation? Ocommand Line Arguments Does the created string end in '\0'? Read the documentation (man pages) Each string function has its own expectations and guarantees

Nebraska

Nebraska

Scanning a Full Line III

Char read_line[80]; gets(read_line); printf("I read your line as \"%s\"\n", read_line) • Dangerous: If the user enters more than 79 characters, no room for null-terminating character • If user enters more than 80 characters: overflow • Can actually be a security hazard • Compiler message: (.text+0x2c5): warning: the 'gets'function is dangerous and should not be used.

4D> 4@> 4E> 4E> E 990

• fgets is safer since you can limit the number of bytes it reads:

char read_line[80];

fgets(read_line,80,stdin)

Reads at most size-1 characters (automatically inserts

null-terminating character)

Takes the endline character out of the standard input, but retains it

in the string

4 D > 4 B > 4 B > 4 B > 9 Q C

```
Nebraska
```

Comparison and Swapping

```
We can perform a sorting algorithm to a list of strings:
```

```
for(i=0; i<num_string-1; i++)</pre>
2
      for(j=i; j<num_string; j++)</pre>
4
5
         if(strcmp(list[j], list[j+1]) > 0)
6
            Swap(list[j],list[j+1]);
7
8
```

What would Swap look like?

```
4 D > 4 B > 4 E > 4 E > E 994 P
```

Nebraska

Comparison and Swapping

Swapping two strings:

```
1 | strcpy(tmp, list[j]);
2
  strcpy(list[j], list[j+1]);
  strcpy(list[j+1], tmp);
```

Careful: how big does tmp need to be?

```
4 D > 4 D > 4 E > 4 E > E 994 P
```

Nebraska

Command Line Arguments I

Up to now, your int main(void) functions have not taken any parameters. To read parameters (delimited by white space) in from the command line, you can use

```
int main(int argc, char *argv[])
```

- argc gives you a count of the number of arguments which are stored in argv
- argv is an array of strings (two-dimensional array of characters)

Nebraska

Command Line Arguments II

- argv: the first element is the program name (ex: argv[0] = a.out)
- Subsequent elements of argv contain strings read from the command line
- Arguments are delimited by whitespace
- You can encapsulate multiple words from the command line using the double quotes

Nebraska

Command Line Arguments III

```
cse> a.out hello world abc 123 "hi everyone"
would result in:
```

```
argc = 6
argv[0] = a.out
argv[1] = hello
argv[2] = world
argv[3] = abc
argv[4] = 123
argv[5] = hi everyone
```

4D> 4@> 4E> 4E> E 990

Nebraska

Command Line Arguments IV

```
commandLineArgs.c
int main(int argc, char *argv[])
   printf("You entered %d arguments.\n",argc-1);
printf("Program Name: %s\n",argv[0]);
  print( riogram wame. %s\n ,argv[0]),
int i;
for(i=1; i<argc; i++)
    printf("\targv[%d] = %s\n",i,argv[i]);</pre>
  return 0;
```

48 / 51

4 m > 4 m >

Common Programming Errors I

 \bullet We usually use functions to compute some value and use the return to send that value back to the main function. However, functions are not allowed to return strings, so we must use what we learned about $% \left\{ 1,2,\ldots ,n\right\}$ input/output parameters

- Know when to use & and when not to
 - Use them for simple data types: int, char, and double
 - Do not use them for whole arrays (strings)

4 D > 4 B > 4 B > 4 B > B 9900

Nebraska

Exercises I

Write a program that takes command line arguments and prints them out one by one. Then sort them in lexicographic order and print them out again.

② A palindrome is a string that is the same backwards and forwards (example: tenet, level). Write a program that reads a string from the command line and determines if it is a palindrome or not. In the case that it is not, make the string a palindrome by concatenating a reversed copy to the end.

Nebraska

Common Programming Errors II

- Be careful not to overflow strings
- Always follow expected formats
- Read the documentation!
- Most important: make sure all strings are null-terminated (a '\0' at the end)
- Just because your program seems to work, doesn't mean it always does (ex: add & to a, b in the sscanf snippet above)
