## Design and Analysis of Algorithms

### Lecture 06 — All-Pairs Shortest Paths (Chapter 25)

Stephen Scott  
(Adapted from Vinodchandran N. Variyam)

sscott@cse.unl.edu

## Introduction

- ▶ Similar to SSSP, but find shortest paths for all pairs of vertices
- ▶ Given a weighted, directed graph  $G = (V, E)$  with weight function  $w : E \rightarrow \mathbb{R}$ , find  $\delta(u, v)$  for all  $(u, v) \in V \times V$
- ▶ One solution: Run an algorithm for SSSP  $|V|$  times, treating each vertex in  $V$  as a source
  - ▶ If no negative weight edges, use Dijkstra's algorithm, for time complexity of  $O(|V|^3 + |V||E|) = O(|V|^3)$  for array implementation,  $O(|V||E| \log |V|)$  if heap used
  - ▶ If negative weight edges, use Bellman-Ford and get  $O(|V|^2|E|)$  time algorithm, which is  $O(|V|^4)$  if graph dense
- ▶ Can we do better?
  - ▶ Matrix multiplication-style algorithm:  $\Theta(|V|^3 \log |V|)$
  - ▶ Floyd-Warshall algorithm:  $\Theta(|V|^3)$
  - ▶ Both algorithms handle negative weight edges

## Adjacency Matrix Representation

- ▶ Will use adjacency matrix representation
- ▶ Assume vertices are numbered:  $V = \{1, 2, \dots, n\}$
- ▶ Input to our algorithms will be  $n \times n$  matrix  $W$ :

$$w_{ij} = \begin{cases} 0 & \text{if } i = j \\ \text{weight of edge } (i, j) & \text{if } (i, j) \in E \\ \infty & \text{if } (i, j) \notin E \end{cases}$$

- ▶ For now, assume negative weight cycles are absent
- ▶ In addition to distance matrices  $L$  and  $D$  produced by algorithms, can also build *predecessor matrix*  $\Pi$ , where  $\pi_{ij}$  = predecessor of  $j$  on a shortest path from  $i$  to  $j$ , or NIL if  $i = j$  or no path exists
  - ▶ Well-defined due to optimal substructure property

## Print-All-Pairs-Shortest-Path( $\Pi, i, j$ )

```

1 if i == j then
2   print i
3 else if  $\pi_{ij} == \text{NIL}$  then
4   print "no path from " i " to " j " exists"
5 else
6   PRINT-ALL-PAIRS-SHORTEST-PATH( $\Pi, i, \pi_{ij}$ )
7   print j
8
```

## Shortest Paths and Matrix Multiplication

- ▶ Will maintain a series of matrices  $L^{(m)} = (\ell_{ij}^{(m)})$ , where  $\ell_{ij}^{(m)}$  = the minimum weight of any path from  $i$  to  $j$  that uses at most  $m$  edges
  - ▶ Special case:  $\ell_{ij}^{(0)} = 0$  if  $i = j$ ,  $\infty$  otherwise

$$\ell_{13}^{(0)} = \infty, \ell_{13}^{(1)} = 8, \ell_{13}^{(2)} = 7$$

## Recursive Solution

- ▶ Exploit optimal substructure property to get a recursive definition of  $\ell_{ij}^{(m)}$
- ▶ To follow shortest path from  $i$  to  $j$  using at most  $m$  edges, either:
  1. Take shortest path from  $i$  to  $j$  using  $\leq m-1$  edges and stay put, or
  2. Take shortest path from  $i$  to some  $k$  using  $\leq m-1$  edges and traverse edge  $(k, j)$

$$\ell_{ij}^{(m)} = \min \left( \ell_{ij}^{(m-1)}, \min_{1 \leq k \leq n} \left( \ell_{ik}^{(m-1)} + w_{kj} \right) \right)$$

- ▶ Since  $w_{jj} = 0$  for all  $j$ , simplify to

$$\ell_{ij}^{(m)} = \min_{1 \leq k \leq n} \left( \ell_{ik}^{(m-1)} + w_{kj} \right)$$

- ▶ If no negative weight cycles, then since all shortest paths have  $\leq n-1$  edges,

$$\delta(i, j) = \ell_{ij}^{(n-1)} = \ell_{ij}^{(n)} = \ell_{ij}^{(n+1)} = \dots$$

## Bottum-Up Computation of $L$ Matrices

- ▶ Start with weight matrix  $W$  and compute series of matrices  $L^{(1)}, L^{(2)}, \dots, L^{(n-1)}$
- ▶ Core of the algorithm is a routine to compute  $L^{(m+1)}$  given  $L^{(m)}$  and  $W$
- ▶ Start with  $L^{(1)} = W$ , and iteratively compute new  $L$  matrices until we get  $L^{(n-1)}$ 
  - ▶ Why is  $L^{(1)} = W$ ?
- ▶ Can we detect negative-weight cycles with this algorithm? How?

## Extend-Shortest-Paths( $L, W$ )

```

1  n = number of rows of L      // This is  $L^{(m)}$ 
2  create new  $n \times n$  matrix  $L'$  // This will be  $L^{(m+1)}$ 
3  for i = 1 to n do
4      for j = 1 to n do
5           $\ell'_{ij} = \infty$ 
6          for k = 1 to n do
7               $\ell'_{ij} = \min(\ell'_{ij}, \ell_{ik} + w_{kj})$ 
8          end
9      end
10 end
11 return  $L'$ 

```

## Slow-All-Pairs-Shortest-Paths( $W$ )

```

1  n = number of rows of W
2   $L^{(1)} = W$ 
3  for m = 2 to n - 1 do
4       $L^{(m)} = \text{EXTEND-SHORTEST-PATHS}(L^{(m-1)}, W)$ 
5  end
6  return  $L^{(n-1)}$ 

```

## Example

$$L^{(1)} = \begin{pmatrix} 0 & 3 & 2 & -4 & 7 \\ \infty & 0 & \infty & 1 & \infty \\ \infty & 4 & 0 & \infty & \infty \\ 2 & \infty & -5 & 0 & \infty \\ \infty & \infty & \infty & 6 & 0 \end{pmatrix} \quad L^{(2)} = \begin{pmatrix} 0 & 3 & 8 & 2 & -4 \\ 3 & 0 & -4 & 1 & 7 \\ \infty & 4 & 0 & 5 & 11 \\ 2 & -1 & -5 & 0 & -2 \\ 8 & \infty & 1 & 6 & 0 \end{pmatrix}$$

$$L^{(3)} = \begin{pmatrix} 0 & 3 & -3 & 2 & -4 \\ 3 & 0 & -4 & 1 & -1 \\ 7 & 4 & 0 & 5 & 11 \\ 2 & -1 & -5 & 0 & -2 \\ 8 & 5 & 1 & 6 & 0 \end{pmatrix} \quad L^{(4)} = \begin{pmatrix} 0 & 1 & -3 & 2 & -4 \\ 3 & 0 & -4 & 1 & -1 \\ 7 & 4 & 0 & 5 & 3 \\ 2 & -1 & -5 & 0 & -2 \\ 8 & 5 & 1 & 6 & 0 \end{pmatrix}$$

## Improving Running Time

- ▶ What is time complexity of SLOW-ALL-PAIRS-SHORTEST-PATHS?
- ▶ Can we do better?
- ▶ Note that if, in EXTEND-SHORTEST-PATHS, we change  $+$  to multiplication and  $\min$  to  $\odot$ , get matrix multiplication of  $L$  and  $W$
- ▶ If we let  $\odot$  represent this "multiplication" operator, then SLOW-ALL-PAIRS-SHORTEST-PATHS computes

$$\begin{aligned}
 L^{(2)} &= L^{(1)} \odot W = W^{\odot 2}, \\
 L^{(3)} &= L^{(2)} \odot W = W^{\odot 3}, \\
 &\vdots \\
 L^{(n-1)} &= L^{(n-2)} \odot W = W^{\odot n-1}
 \end{aligned}$$

- ▶ Thus, we get  $L^{(n-1)}$  by iteratively "multiplying"  $W$  via EXTEND-SHORTEST-PATHS

## Improving Running Time (2)

- ▶ But we don't need every  $L^{(m)}$ ; we only want  $L^{(n-1)}$
- ▶ E.g. if we want to compute  $7^{64}$ , we could multiply 7 by itself 64 times, or we could square it 6 times
- ▶ In our application, once we have a handle on  $L^{((n-1)/2)}$ , we can immediately get  $L^{(n-1)}$  from one call to EXTEND-SHORTEST-PATHS( $L^{((n-1)/2)}, L^{((n-1)/2)}$ )
- ▶ Of course, we can similarly get  $L^{((n-1)/2)}$  from "squaring"  $L^{((n-1)/4)}$ , and so on
- ▶ Starting from the beginning, we initialize  $L^{(1)} = W$ , then compute  $L^{(2)} = L^{(1)} \odot L^{(1)}$ ,  $L^{(4)} = L^{(2)} \odot L^{(2)}$ ,  $L^{(8)} = L^{(4)} \odot L^{(4)}$ , and so on
- ▶ What happens if  $n - 1$  is not a power of 2 and we "overshoot" it?
- ▶ How many steps of repeated squaring do we need to make?
- ▶ What is time complexity of this new algorithm?

## Faster-All-Pairs-Shortest-Paths( $W$ )

```

1   $n$  = number of rows of  $W$ 
2   $L^{(1)} = W$ 
3   $m = 1$ 
4  while  $m < n - 1$  do
5       $L^{(2m)} = \text{EXTEND-SHORTEST-PATHS}(L^{(m)}, L^{(m)})$ 
6       $m = 2m$ 
7  end
8  return  $L^{(m)}$ 

```

## Floyd-Warshall Algorithm

- Shaves the logarithmic factor off of the previous algorithm
- As with previous algorithm, start by assuming that there are no negative weight cycles; can detect negative weight cycles the same way as before
- Considers a different way to decompose shortest paths, based on the notion of an *intermediate vertex*
  - If simple path  $p = \langle v_1, v_2, v_3, \dots, v_{\ell-1}, v_{\ell} \rangle$ , then the set of intermediate vertices is  $\{v_2, v_3, \dots, v_{\ell-1}\}$

## Structure of Shortest Path

- Again, let  $V = \{1, \dots, n\}$ , and fix  $i, j \in V$
- For some  $1 \leq k \leq n$ , consider set of vertices  $V_k = \{1, \dots, k\}$
- Now consider all paths from  $i$  to  $j$  whose intermediate vertices come from  $V_k$  and let  $p$  be the minimum-weight path from them
- Is  $k \in p$ ?
  1. If not, then all intermediate vertices of  $p$  are in  $V_{k-1}$ , and a SP from  $i$  to  $j$  based on  $V_{k-1}$  is also a SP from  $i$  to  $j$  based on  $V_k$
  2. If so, then we can decompose  $p$  into  $i \xrightarrow{p_1} k \xrightarrow{p_2} j$ , where  $p_1$  and  $p_2$  are each shortest paths based on  $V_{k-1}$

## Structure of Shortest Path (2)

## Recursive Solution

- What does this mean?
- It means that the shortest path from  $i$  to  $j$  based on  $V_k$  is either going to be the same as that based on  $V_{k-1}$ , or it is going to go through  $k$
- In the latter case, a shortest path from  $i$  to  $j$  based on  $V_k$  is going to be a shortest path from  $i$  to  $k$  based on  $V_{k-1}$ , followed by a shortest path from  $k$  to  $j$  based on  $V_{k-1}$
- Let matrix  $D^{(k)} = (d_{ij}^{(k)})$ , where  $d_{ij}^{(k)}$  = weight of a shortest path from  $i$  to  $j$  based on  $V_k$ :

$$d_{ij}^{(k)} = \begin{cases} w_{ij} & \text{if } k = 0 \\ \min(d_{ij}^{(k-1)}, d_{ik}^{(k-1)} + d_{kj}^{(k-1)}) & \text{if } k \geq 1 \end{cases}$$

- Since all SPs are based on  $V_n = V$ , we get  $d_{ij}^{(n)} = \delta(i, j)$  for all  $i, j \in V$

## Floyd-Warshall( $W$ )

```

1   $n$  = number of rows of  $W$ 
2   $D^{(0)} = W$ 
3  for  $k = 1$  to  $n$  do
4      for  $i = 1$  to  $n$  do
5          for  $j = 1$  to  $n$  do
6               $d_{ij}^{(k)} = \min(d_{ij}^{(k-1)}, d_{ik}^{(k-1)} + d_{kj}^{(k-1)})$ 
7          end
8      end
9  end
10 return  $D^{(n)}$ 

```

## Floyd-Warshall Example

Split into teams, and simulate Floyd-Warshall on this example:

Navigation icons: back, forward, search, etc.

## Transitive Closure

- Used to determine whether paths exist between pairs of vertices
- Given directed, unweighted graph  $G = (V, E)$  where  $V = \{1, \dots, n\}$ , the *transitive closure* of  $G$  is  $G^* = (V, E^*)$ , where

$$E^* = \{(i, j) : \text{there is a path from } i \text{ to } j \text{ in } G\}$$

- How can we directly apply Floyd-Warshall to find  $E^*$ ?
- Simpler way: Define matrix  $T$  similarly to  $D$ :

$$t_{ij}^{(0)} = \begin{cases} 0 & \text{if } i \neq j \text{ and } (i, j) \notin E \\ 1 & \text{if } i = j \text{ or } (i, j) \in E \end{cases}$$

$$t_{ij}^{(k)} = t_{ij}^{(k-1)} \vee (t_{ik}^{(k-1)} \wedge t_{kj}^{(k-1)})$$

- I.e. you can reach  $j$  from  $i$  using  $V_k$  if you can do so using  $V_{k-1}$  or if you can reach  $k$  from  $i$  and reach  $j$  from  $k$ , both using  $V_{k-1}$

Navigation icons: back, forward, search, etc.

## Transitive-Closure( $G$ )

```

1 allocate and initialize  $n \times n$  matrix  $T^{(0)}$ 
2 for  $k = 1$  to  $n$  do
3   allocate  $n \times n$  matrix  $T^{(k)}$ 
4   for  $i = 1$  to  $n$  do
5     for  $j = 1$  to  $n$  do
6        $t_{ij}^{(k)} = t_{ij}^{(k-1)} \vee (t_{ik}^{(k-1)} \wedge t_{kj}^{(k-1)})$ 
7     end
8   end
9 end
10 return  $T^{(n)}$ 

```

Navigation icons: back, forward, search, etc.

## Example

$$T^{(0)} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 \\ 0 & 1 & 1 & 0 \\ 1 & 0 & 1 & 1 \end{pmatrix} \quad T^{(1)} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 \\ 0 & 1 & 1 & 0 \\ 1 & 0 & 1 & 1 \end{pmatrix} \quad T^{(2)} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 \\ 0 & 1 & 1 & 1 \\ 1 & 0 & 1 & 1 \end{pmatrix}$$

$$T^{(3)} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 \\ 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \end{pmatrix} \quad T^{(4)} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \end{pmatrix}$$

Navigation icons: back, forward, search, etc.

## Analysis

- Like Floyd-Warshall, time complexity is officially  $\Theta(n^3)$
- However, use of 0s and 1s exclusively allows implementations to use bitwise operations to speed things up significantly, processing bits in batch, a word at a time
- Also saves space
- Another space saver: Can update the  $T$  matrix (and F-W's  $D$  matrix) in place rather than allocating a new matrix for each step (Exercise 25.2-4)

Navigation icons: back, forward, search, etc.
