Computer Science & Engineering 423/823 Design and Analysis of Algorithms Lecture 07 — All-Pairs Shortest Paths (Chapter 25)

Stephen Scott (Adapted from Vinodchandran N. Variyam)

sscott@cse.unl.edu

#### Introduction

- Similar to SSSP, but find shortest paths for all pairs of vertices
- Given a weighted, directed graph G = (V, E) with weight function w : E → ℝ, find δ(u, v) for all (u, v) ∈ V × V
- One solution: Run an algorithm for SSSP |V| times, treating each vertex in V as a source
  - If no negative weight edges, use Dijkstra's algorithm, for time complexity of O(|V|<sup>3</sup> + |V||E|) = O(|V|<sup>3</sup>) for array implementation, O(|V||E| log |V|) if heap used
  - ► If negative weight edges, use Bellman-Ford and get O(|V|<sup>2</sup>|E|) time algorithm, which is O(|V|<sup>4</sup>) if graph dense
- Can we do better?
  - Matrix multiplication-style algorithm:  $\Theta(|V|^3 \log |V|)$
  - Floyd-Warshall algorithm:  $\Theta(|V|^3)$
  - Both algorithms handle negative weight edges

### Adjacency Matrix Representation

- Will use adjacency matrix representation
- Assume vertices are numbered:  $V = \{1, 2, ..., n\}$
- Input to our algorithms will be  $n \times n$  matrix W:

$$w_{ij} = \begin{cases} 0 & \text{if } i = j \\ \text{weight of edge } (i,j) & \text{if } (i,j) \in E \\ \infty & \text{if } (i,j) \notin E \end{cases}$$

- For now, assume negative weight cycles are absent
- In addition to distance matrices L and D produced by algorithms, can also build predecessor matrix Π, where π<sub>ij</sub> = predecessor of j on a shortest path from i to j, or NIL if i = j or no path exists
  - Well-defined due to optimal substructure property

## Print-All-Pairs-Shortest-Path $(\Pi, i, j)$

```
1 if i == j then

2 | print i

3 else if \pi_{ij} == NIL then

4 | print "no path from " i " to " j " exists"

5 else

6 | PRINT-ALL-PAIRS-SHORTEST-PATH(\Pi, i, \pi_{ij})

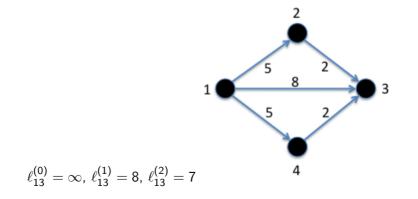

7 | print j

8
```

#### Shortest Paths and Matrix Multiplication

- ▶ Will maintain a series of matrices  $L^{(m)} = (\ell_{ij}^{(m)})$ , where  $\ell_{ij}^{(m)} =$  the minimum weight of any path from *i* to *j* that uses at most *m* edges
  - Special case:  $\ell_{ij}^{(0)} = 0$  if i = j,  $\infty$  otherwise

#### **Recursive Solution**

- Exploit optimal substructure property to get a recursive definition of  $\ell_{ii}^{(m)}$
- ▶ To follow shortest path from *i* to *j* using at most *m* edges, either:
  - 1. Take shortest path from i to j using  $\leq m-1$  edges and stay put, or
  - 2. Take shortest path from *i* to some *k* using  $\leq m 1$  edges and traverse edge (k, j)

$$\ell_{ij}^{(m)} = \min\left(\ell_{ij}^{(m-1)}, \min_{1 \leq k \leq n}\left(\ell_{ik}^{(m-1)} + w_{kj}
ight)
ight)$$

• Since  $w_{jj} = 0$  for all j, simplify to

$$\ell_{ij}^{(m)} = \min_{1 \le k \le n} \left( \ell_{ik}^{(m-1)} + w_{kj} \right)$$

► If no negative weight cycles, then since all shortest paths have ≤ n - 1 edges,

$$\delta(i,j) = \ell_{ij}^{(n-1)} = \ell_{ij}^{(n)} = \ell_{ij}^{(n+1)} = \cdots$$

## Bottum-Up Computation of L Matrices

- Start with weight matrix W and compute series of matrices L<sup>(1)</sup>, L<sup>(2)</sup>,..., L<sup>(n-1)</sup>
- Core of the algorithm is a routine to compute  $L^{(m+1)}$  given  $L^{(m)}$  and W
- Start with L<sup>(1)</sup> = W, and iteratively compute new L matrices until we get L<sup>(n-1)</sup>

- Why is  $L^{(1)} == W$ ?
- Can we detect negative-weight cycles with this algorithm? How?

Extend-Shortest-Paths(L, W)

1 n = number of rows of L // This is  $L^{(m)}$ 2 create new  $n \times n$  matrix L' // This will be  $L^{(m+1)}$ 3 for i = 1 to n do for j = 1 to n do 4  $| \ell'_{ii} = \infty$ 5 for k = 1 to n do 6  $| \qquad | \qquad \ell'_{ii} = \min\left(\ell'_{ii}, \ell_{ik} + w_{ki}\right)$ 7 end 8 end 9 10 end 11 return L'

◆□ > ◆□ > ◆臣 > ◆臣 > 善臣 - のへぐ

### Slow-All-Pairs-Shortest-Paths(W)

```
1 n = number of rows of W

2 L^{(1)} = W

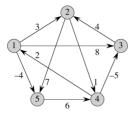

3 for m = 2 to n - 1 do

4 | L^{(m)} = \text{EXTEND-SHORTEST-PATHS}(L^{(m-1)}, W)

5 end

6 return L^{(n-1)}
```

# Example

$$L^{(1)} = \begin{pmatrix} 0 & 3 & 8 & \infty & -4 \\ \infty & 0 & \infty & 1 & 7 \\ \infty & 4 & 0 & \infty & \infty \\ 2 & \infty & -5 & 0 & \infty \\ \infty & \infty & \infty & 6 & 0 \end{pmatrix} \qquad L^{(2)} = \begin{pmatrix} 0 & 3 & 8 & 2 & -4 \\ 3 & 0 & -4 & 1 & 7 \\ \infty & 4 & 0 & 5 & 11 \\ 2 & -1 & -5 & 0 & -2 \\ 8 & \infty & 1 & 6 & 0 \end{pmatrix}$$
$$L^{(3)} = \begin{pmatrix} 0 & 3 & -3 & 2 & -4 \\ 3 & 0 & -4 & 1 & -1 \\ 7 & 4 & 0 & 5 & 11 \\ 2 & -1 & -5 & 0 & -2 \\ 8 & 5 & 1 & 6 & 0 \end{pmatrix} \qquad L^{(4)} = \begin{pmatrix} 0 & 1 & -3 & 2 & -4 \\ 3 & 0 & -4 & 1 & -1 \\ 7 & 4 & 0 & 5 & 3 \\ 2 & -1 & -5 & 0 & -2 \\ 8 & 5 & 1 & 6 & 0 \end{pmatrix}$$

## Improving Running Time

- ▶ What is time complexity of SLOW-ALL-PAIRS-SHORTEST-PATHS?
- Can we do better?
- Note that if, in EXTEND-SHORTEST-PATHS, we change + to multiplication and min to +, get matrix multiplication of L and W
- ► If we let ⊙ represent this "multiplication" operator, then SLOW-ALL-PAIRS-SHORTEST-PATHS computes

$$L^{(2)} = L^{(1)} \odot W = W^{(2)},$$
  

$$L^{(3)} = L^{(2)} \odot W = W^{(3)},$$
  

$$\vdots$$
  

$$L^{(n-1)} = L^{(n-2)} \odot W = W^{n-1}$$

► Thus, we get L<sup>(n-1)</sup> by iteratively "multiplying" W via EXTEND-SHORTEST-PATHS

## Improving Running Time (2)

- But we don't need every  $L^{(m)}$ ; we only want  $L^{(n-1)}$
- E.g., if we want to compute 7<sup>64</sup>, we could multiply 7 by itself 64 times, or we could square it 6 times
- In our application, once we have a handle on L<sup>((n-1)/2)</sup>, we can immediately get L<sup>(n-1)</sup> from one call to EXTEND-SHORTEST-PATHS(L<sup>((n-1)/2)</sup>, L<sup>((n-1)/2)</sup>)
- Of course, we can similarly get  $L^{((n-1)/2)}$  from "squaring"  $L^{((n-1)/4)}$ , and so on
- ▶ Starting from the beginning, we initialize  $L^{(1)} = W$ , then compute  $L^{(2)} = L^{(1)} \odot L^{(1)}$ ,  $L^{(4)} = L^{(2)} \odot L^{(2)}$ ,  $L^{(8)} = L^{(4)} \odot L^{(4)}$ , and so on
- What happens if n 1 is not a power of 2 and we "overshoot" it?
- How many steps of repeated squaring do we need to make?
- What is time complexity of this new algorithm?

### Faster-All-Pairs-Shortest-Paths(W)

1 n = number of rows of W2  $L^{(1)} = W$ 3 m = 14 while m < n - 1 do 5  $\begin{vmatrix} L^{(2m)} = \text{EXTEND-SHORTEST-PATHS}(L^{(m)}, L^{(m)}) \\ m = 2m$ 7 end 8 return  $L^{(m)}$

## Floyd-Warshall Algorithm

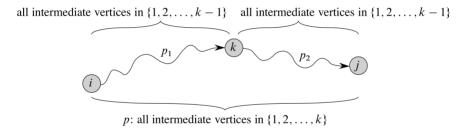

- Shaves the logarithmic factor off of the previous algorithm
- As with previous algorithm, start by assuming that there are no negative weight cycles; can detect negative weight cycles the same way as before
- Considers a different way to decompose shortest paths, based on the notion of an *intermediate vertex*
  - If simple path p = ⟨v<sub>1</sub>, v<sub>2</sub>, v<sub>3</sub>,..., v<sub>ℓ-1</sub>, v<sub>ℓ</sub>⟩, then the set of intermediate vertices is {v<sub>2</sub>, v<sub>3</sub>,..., v<sub>ℓ-1</sub>}

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● ● ● ●

#### Structure of Shortest Path

- Again, let  $V = \{1, \ldots, n\}$ , and fix  $i, j \in V$
- ▶ For some  $1 \le k \le n$ , consider set of vertices  $V_k = \{1, ..., k\}$
- Now consider all paths from i to j whose intermediate vertices come from V<sub>k</sub> and let p be a minimum-weight path from them
- ► Is k ∈ p?
  - 1. If not, then all intermediate vertices of p are in  $V_{k-1}$ , and a SP from i to j based on  $V_{k-1}$  is also a SP from i to j based on  $V_k$
  - 2. If so, then we can decompose p into  $i \stackrel{p_1}{\rightsquigarrow} k \stackrel{p_2}{\rightsquigarrow} j$ , where  $p_1$  and  $p_2$  are each shortest paths based on  $V_{k-1}$

## Structure of Shortest Path (2)

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● ● ● ●

#### **Recursive Solution**

- What does this mean?
- It means that a shortest path from i to j based on V<sub>k</sub> is either going to be the same as that based on V<sub>k-1</sub>, or it is going to go through k
- ► In the latter case, a shortest path from i to j based on V<sub>k</sub> is going to be a shortest path from i to k based on V<sub>k-1</sub>, followed by a shortest path from k to j based on V<sub>k-1</sub>
- Let matrix  $D^{(k)} = (d_{ij}^{(k)})$ , where  $d_{ij}^{(k)} =$  weight of a shortest path from *i* to *j* based on  $V_k$ :

$$d_{ij}^{(k)} = \left\{ egin{array}{ll} w_{ij} & ext{if } k = 0 \ \min\left(d_{ij}^{(k-1)}, d_{ik}^{(k-1)} + d_{kj}^{(k-1)}
ight) & ext{if } k \geq 1 \end{array} 
ight.$$

▶ Since all SPs are based on  $V_n = V$ , we get  $d_{ij}^{(n)} = \delta(i,j)$  for all  $i,j \in V$ 

## Floyd-Warshall(W)

n = number of rows of W $D^{(0)} = W$ 3 for k = 1 to n do  $\left| \begin{array}{c} \text{for } i = 1 \text{ to } n \text{ do} \\ 5 \\ 6 \\ 6 \\ 7 \\ 8 \end{array} \right| \left| \begin{array}{c} \text{for } j = 1 \text{ to } n \text{ do} \\ d_{ij}^{(k)} = \min \left( d_{ij}^{(k-1)}, d_{ik}^{(k-1)} + d_{kj}^{(k-1)} \right) \\ 0 \\ 8 \\ 8 \\ 1 \\ 10 \\ \text{return } D^{(n)} \end{array}$ 

▲□▶ ▲□▶ ▲三▶ ▲三▶ ▲□▶ ▲□▶

### **Transitive Closure**

- Used to determine whether paths exist between pairs of vertices
- ▶ Given directed, unweighted graph G = (V, E) where V = {1,..., n}, the *transitive closure* of G is G\* = (V, E\*), where

 $E^* = \{(i, j) : \text{there is a path from } i \text{ to } j \text{ in } G\}$ 

- ▶ How can we directly apply Floyd-Warshall to find E\*?
- Simpler way: Define matrix T similarly to D:

$$t_{ij}^{(0)} = \left\{egin{array}{ll} 0 & ext{if } i 
eq j ext{ and } (i,j) 
eq E \ 1 & ext{if } i = j ext{ or } (i,j) \in E \ t_{ij}^{(k)} = t_{ij}^{(k-1)} \lor \left(t_{ik}^{(k-1)} \land t_{kj}^{(k-1)}
ight)$$

► I.e., you can reach j from i using V<sub>k</sub> if you can do so using V<sub>k-1</sub> or if you can reach k from i and reach j from k, both using V<sub>k-1</sub>

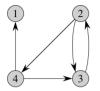

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● ● ● ●

## Transitive-Closure(G)

1 allocate and initialize  $n \times n$  matrix  $T^{(0)}$ 2 for k = 1 to n do 3 allocate  $n \times n$  matrix  $T^{(k)}$ 4 for i = 1 to n do 5 for j = 1 to n do 6  $| t_{ij}^{(k)} = t_{ij}^{(k-1)} \vee t_{ik}^{(k-1)} \wedge t_{kj}^{(k-1)}$ 7 end 8 end 9 end 10 return  $T^{(n)}$ 

◆□ > ◆□ > ◆臣 > ◆臣 > 善臣 - のへぐ

Example

## Analysis

- Like Floyd-Warshall, time complexity is officially  $\Theta(n^3)$
- However, use of 0s and 1s exclusively allows implementations to use bitwise operations to speed things up significantly, processing bits in batch, a word at a time
- Also saves space
- Another space saver: Can update the T matrix (and F-W's D matrix) in place rather than allocating a new matrix for each step (Exercise 25.2-4)
