Computer Science & Engineering 423/823 Design and Analysis of Algorithms Lecture 06 — Minimum-Weight Spanning Trees (Chapter 23)

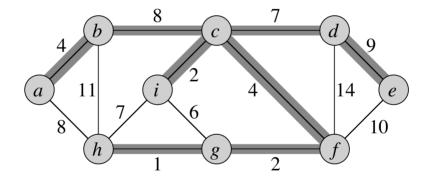

Stephen Scott and Vinodchandran N. Variyam

sscott@cse.unl.edu

Introduction

- Given a connected, undirected graph G = (V, E), a spanning tree is an acyclic subset T ⊆ E that connects all vertices in V
 - T acyclic \Rightarrow a tree
 - T connects all vertices \Rightarrow spans G
- ▶ If G is weighted, then T's weight is $w(T) = \sum_{(u,v) \in T} w(u,v)$
- A minimum weight spanning tree (or minimum spanning tree, or MST) is a spanning tree of minimum weight
 - Not necessarily unique
- Applications: anything where one needs to connect all nodes with minimum cost, e.g., wires on a circuit board or fiber cable in a network

MST Example

Kruskal's Algorithm

- Greedy algorithm: Make the locally best choice at each step
- Starts by declaring each vertex to be its own tree (so all nodes together make a forest)
- Iteratively identify the minimum-weight edge (u, v) that connects two distinct trees, and add it to the MST T, merging u's tree with v's tree

MST-Kruskal(G, w)

 $A = \emptyset$ ² for each vertex $v \in V$ do MAKE-SET(v)3 4 end 5 sort edges in E into nondecreasing order by weight w6 for each edge $(u, v) \in E$, taken in nondecreasing order do if FIND-SET(u) \neq FIND-SET(v) then 7 $A = A \cup \{(u, v)\}$ 8 UNION(u, v)9 10 11 end 12 return A

More on Kruskal's Algorithm

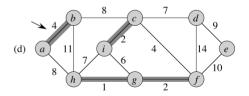

- FIND-SET(u) returns a representative element from the set (tree) that contains u
- UNION(u, v) combines u's tree to v's tree
- > These functions are based on the disjoint-set data structure
- More on this later

Example (1)

 Example (2)

Example (3)

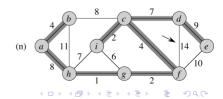

Disjoint-Set Data Structure

- ▶ Given a universe U = {x₁,...,x_n} of elements (e.g., the vertices in a graph G), a DSDS maintains a collection S = {S₁,...,S_k} of disjoint sets of elements such that
 - Each element x_i is in exactly one set S_j
 - ▶ No set S_j is empty
- Membership in sets is dynamic (changes as program progresses)
- Each set $S \in S$ has a **representative element** $x \in S$
- Chapter 21

Disjoint-Set Data Structure (2)

- DSDS implementations support the following functions:
 - MAKE-SET(x) takes element x and creates new set {x}; returns pointer to x as set's representative
 - UNION(x, y) takes x's set (S_x) and y's set (S_y , assumed disjoint from S_x), merges them, destroys S_x and S_y , and returns representative for new set from $S_x \cup S_y$
 - FIND-SET(x) returns a pointer to the representative of the unique set that contains x
- Section 21.3: can perform d D-S operations on e elements in time O(d α(e)), where α(e) = o(lg* e) = o(log e) is very slowly growing:

$$\alpha(e) = \begin{cases} 0 & \text{if } 0 \le e \le 2\\ 1 & \text{if } e = 3\\ 2 & \text{if } 4 \le e \le 7\\ 3 & \text{if } 8 \le e \le 2047\\ 4 & \text{if } 2048 \le e \le 2^{2048} \ (\gg 10^{600}) \end{cases} \quad \text{Ig}^*(e) = \begin{cases} 0 & \text{if } e \le 1\\ 1 & \text{if } 1 < e \le 2\\ 2 & \text{if } 2 < e \le 4\\ 3 & \text{if } 4 < e \le 16\\ 4 & \text{if } 16 < e \le 65536\\ 5 & \text{if } 65536 < e \le 2^{65536} \end{cases}$$

Analysis of Kruskal's Algorithm

- ► Sorting edges takes time O(|E| log |E|)
- Number of disjoint-set operations is O(|V| + |E|) on O(|V|) elements, which can be done in time O((|V| + |E|) α(|V|)) = O(|E| α(|V|)) since |E| ≥ |V| − 1
- Since $\alpha(|V|) = o(\log |V|) = O(\log |E|)$, we get total time of $O(|E|\log |E|) = O(|E|\log |V|)$ since $\log |E| = O(\log |V|)$

Prim's Algorithm

- Greedy algorithm, like Kruskal's
- In contrast to Kruskal's, Prim's algorithm maintains a single tree rather than a forest
- Starts with an arbitrary tree root r
- Repeatedly finds a minimum-weight edge that is incident to a node not yet in tree

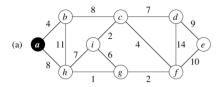

MST-Prim(G, w, r)

 $1 A = \emptyset$ 2 for each vertex $v \in V$ do $key[v] = \infty$ 3 $\pi[v] = \text{NIL}$ 4 5 end 6 key[r] = 0 $7 \quad Q = V$ 8 while $Q \neq \emptyset$ do u = Extract-Min(Q)9 for each $v \in Adj[u]$ do 10 if $v \in Q$ and w(u, v) < key[v] then 11 $\pi[v] = u$ 12 key[v] = w(u, v)13 14 15 end 16 end

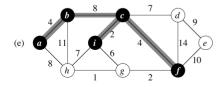

More on Prim's Algorithm

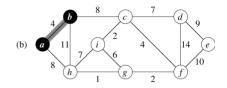

- key[v] is the weight of the minimum weight edge from v to any node already in MST
- EXTRACT-MIN uses a minimum heap (minimum priority queue) data structure
 - Binary tree where the key at each node is \leq keys of its children
 - Thus minimum value always at top
 - Any subtree is also a heap
 - Height of tree is $\Theta(\log n)$
 - Can build heap on n elements in O(n) time
 - After returning the minimum, can filter new minimum to top in time O(log n)
 - Based on Chapter 6

Analysis of Prim's Algorithm

Invariant: Prior to each iteration of the while loop:

- 1. Nodes already in MST are exactly those in $V \setminus Q$
- 2. For all vertices $v \in Q$, if $\pi[v] \neq \text{NIL}$, then $key[v] < \infty$ and key[v] is the weight of the lightest edge that connects v to a node already in the tree
- ► Time complexity:
 - Building heap takes time O(|V|)
 - Make |V| calls to EXTRACT-MIN, each taking time $O(\log |V|)$
 - For loop iterates O(|E|) times
 - In for loop, need constant time to check for queue membership and O(log |V|) time for decreasing v's key and updating heap
 - ▶ Yields total time of $O(|V| \log |V| + |E| \log |V|) = O(|E| \log |V|)$
 - Can decrease total time to $O(|E| + |V| \log |V|)$ using Fibonacci heaps

Proof of Correctness of Both Algorithms

- Both algorithms use greedy approach for optimality
- Maintain invariant that at any time, set of edges A selected so far is subset of some MST
 - \Rightarrow Optimal substructure property
- ► Each iteration of each algorithm looks for a safe edge e such that A ∪ {e} is also a subset of an MST
 - \Rightarrow Greedy choice
- Prove invariant via use of cut (S, V S) that respects A (no edges span cut)

Proof of Correctness of Both Algorithms (2)

Theorem: Let A ⊆ E be included in some MST of G, (S, V − S) be a cut respecting A, and (u, v) ∈ E be a minimum-weight edge crossing cut. Then (u, v) is a safe edge for A.

Proof:

- Let T be an MST including A and not including (u, v)
- Let p be path from u to v in T, and (x, y) be edge from p crossing cut (⇒ not in A)
- Since T is a spanning tree, so is $T' = T \{(x, y)\} \cup \{(u, v)\}$
- Both (u, v) and (x, y) cross cut, so $w(u, v) \le w(x, y)$
- So, $w(T') = w(T) w(x, y) + w(u, v) \le w(T)$
- \Rightarrow T' is MST
- \Rightarrow (*u*, *v*) safe for *A* since $A \cup \{(u, v)\} \subseteq T'$

Proof of Correctness of Both Algorithms (3)
