Estimating Generalization Performance

Comparing Learning Algorithms

Other Performance Measures

- Machine learning can generally be distilled to an optimization problem
- Choose a classifier (function, hypothesis) from a set of functions that minimizes an objective function
- Clearly we want part of this function to measure performance on the training set, but this is insufficient

Machine Learning Problems

CSCE 496/896 Lecture 3: Regularization

Stephen Scott and Vinod Variyam

Introduction

Measuring Performance

Regularization

Estimating Generalization Performance

Comparing Learning Algorithms

Other Performance Measures

- Supervised Learning: Algorithm given labeled *training data* and infers function (*hypothesis*) from a family of functions (e.g., set of all ANNs) that is able to predict well on new, unseen examples
 - Classification: Labels come from a finite, discrete set
 - Regression: Labels are real-valued
- Unsupervised Learning: Algorithm is given data without labels and is asked to model its structure
 - Clustering, density estimation
- Reinforcement Learning: Algorithm controls an agent that interacts with its environment and learns good actions in various situations

Measuring Performance

CSCE 496/896 Lecture 3: Regularization

Stephen Scott and Vinod Variyam

Introduction

Measuring Performance

Loss Overfitting

Regularization

Estimating Generalization Performance

Comparing Learning Algorithms

Other Performance Measures

- In any learning problem, need to be able to quantify performance of algorithm
- In supervised learning, we often use **loss function** (or error function) \mathcal{J} for this task
- Given instance x with true label y, if the learner's prediction on x is ŷ, then

$$\mathcal{J}(y, \hat{y})$$

◆□▶ ◆□▶ ◆□▶ ◆□▶ → □ ・ つくぐ

is the loss on that instance

Measuring Performance Examples of Loss Functions

CSCE 496/896 Lecture 3: Regularization

Stephen Scott and Vinod Variyam

Introduction

Measuring Performance

Overfitting

Regularization

Estimating Generalization Performance

Comparing Learning Algorithms

Other Performance Measures • 0-1 Loss: $\mathcal{J}(y, \hat{y}) = 1$ if $y \neq \hat{y}$, 0 otherwise

- Square Loss: $\mathcal{J}(y, \hat{y}) = (y \hat{y})^2$
- Cross-Entropy: $\mathcal{J}(y, \hat{y}) = -y \ln \hat{y} (1 y) \ln (1 \hat{y})$ (y and \hat{y} are considered probabilities of a '1' label)
 - Generalizes to k classes ($i^* =$ correct class):

$$\mathcal{J}(\mathbf{y}, \hat{\mathbf{y}}) = -\sum_{i=1}^{k} y_i \ln \hat{y}_i = -\ln \hat{y}_{i^*}$$

(y is one-hot vector; \hat{y}_i is predicted prob. of class i)

• Hinge Loss: $\mathcal{J}(y, \hat{y}) = \max(0, 1 - y \hat{y})$ (used sometimes for large margin classifiers like SVMs)

All non-negative

Measuring Performance Training Loss

CSCE 496/896 Lecture 3: Regularization

Stephen Scott and Vinod Variyam

Introduction

Measuring Performance

Loss Overfitting

Regularization

Estimating Generalization Performance

Comparing Learning Algorithms

Other Performance Measures • Given a loss function \mathcal{J} and a training set \mathcal{X} , the total loss of the classifier *h* on \mathcal{X} is

$$error_{\mathcal{X}}(h) = \sum_{\boldsymbol{x} \in \mathcal{X}} \mathcal{J}(y_{\boldsymbol{x}}, \hat{y}_{\boldsymbol{x}}) \;\;,$$

▲ロト ▲周 ト ▲ ヨ ト ▲ ヨ ト ・ シ へ つ ヘ

where y_x is x's label and \hat{y}_x is h's prediction

Measuring Performance Expected Loss

CSCE 496/896 Lecture 3: Regularization

Stephen Scott and Vinod Variyam

Introduction

Measuring Performance

Loss Overfitting

Regularization

Estimating Generalization Performance

Comparing Learning Algorithms

Other Performance Measures More importantly, the learner needs to generalize well: Given a new example drawn iid according to unknown probability distribution D, we want to minimize h's expected loss:

$$error_{\mathcal{D}}(h) = \mathbb{E}_{\boldsymbol{x} \sim \mathcal{D}}\left[\mathcal{J}(y_{\boldsymbol{x}}, \hat{y}_{\boldsymbol{x}})\right]$$

◆□▶ ◆□▶ ◆□▶ ◆□▶ → □ ・ つくぐ

• Is minimizing training loss the same as minimizing expected loss?

Measuring Performance Expected vs Training Loss

CSCE 496/896 Lecture 3: Regularization

Stephen Scott and Vinod Variyam

Introduction

Measuring Performance Loss Overfitting

Regularization

Estimating Generalization Performance

Comparing Learning Algorithms

Other Performance Measures

- Sufficiently sophisticated learners (decision trees, multi-layer ANNs) can often achieve arbitrarily small (or zero) loss on a training set
- A hypothesis (e.g., ANN with specific parameters) h overfits the training data X if there is an alternative hypothesis h' such that

 $error_{\mathcal{X}}(h) < error_{\mathcal{X}}(h')$

and

 $error_{\mathcal{D}}(h) > error_{\mathcal{D}}(h')$

Measuring Performance

Measuring Performance Nebraska Overfitting

To generalize well, need to balance training accuracy with simplicity

Regularization Causes of Overfitting

CSCE 496/896 Lecture 3: Regularization

Stephen Scott and Vinod Variyam

Introduction

Measuring Performance

Regularization Causes of Overfitting Early Stopping Parameter Norm Penalties Data Augmentation Multitask Learning Dropout Batch Normalization Others

Estimating Generalization Performance

Comparing Learning Aldorithms

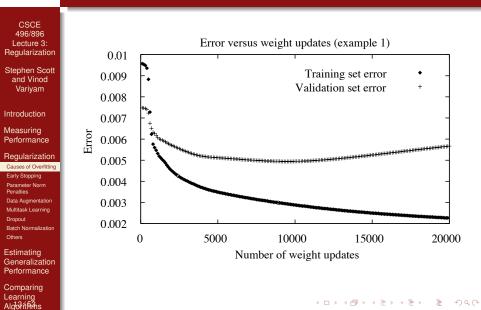

- Generally, if the set of functions \mathcal{H} the learner has to choose from is complex relative to what is required for correctly predicting the labels of \mathcal{X} , there's a larger chance of overfitting due to the large number of "wrong" choices in \mathcal{H}
 - Could be due to an overly sophisticated set of functions
 - E.g., can fit any set of *n* real-valued points with an (n-1)-degree polynomial, but perhaps only degree 2 is needed
 - E.g., using an ANN with 5 hidden layers to solve the logical AND problem
 - Could be due to training an ANN too long
 - Over-training an ANN often leads to weights deviating far from zero
 - Makes the function more non-linear, and more complex

◆□▶ ◆□▶ ◆□▶ ◆□▶ → □ ・ つくぐ

• Often, a larger data set mitigates the problem

Regularization Causes of Overfitting: Overtraining

Regularization Early Stopping

CSCE 496/896 Lecture 3: Regularization

Stephen Scott and Vinod Variyam

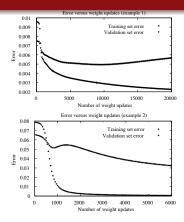

Introduction

Measuring Performance

Regularization Causes of Overfitting Early Stopping Parameter Norm Penalties Data Augmentation Multitask Learning Dropout Batch Normalization Others

Estimating Generalization Performance

Comparing Learning Algorithms

- Danger of stopping too soon
 - "Patience" parameter determines how long to wait
- Can re-start and track best one on separate validation set

Regularization Parameter Norm Penalties

Stephen Scott and Vinod Variyam

Introduction

Measuring Performance

Regularization Causes of Overfitting Early Stopping Parameter Norm Penalties

Data Augmentation Multitask Learning Dropout Batch Normalization Others

Estimating Generalization Performance

Comparing Learning Aldorithins • Still want to minimize training loss, but balance it against a complexity penalty on the parameters used:

$$ilde{\mathcal{I}}(m{ heta}; m{\mathcal{X}}, m{y}) = \mathcal{J}(m{ heta}; m{\mathcal{X}}, m{y}) + lpha \, \Omega(m{ heta})$$

Regularization Parameter Norm Penalties: L² Norm

CSCE 496/896 Lecture 3: Regularization

Stephen Scott and Vinod Variyam

Introduction

Measuring Performance

Regularization Causes of Overfitting Early Stopping Parameter Norm

Parameter Norm Penalties Data Augmentation

Multitask Learning Dropout Batch Normalization

Others

Estimating Generalization Performance

Comparing Learning Aloorithins

- $\Omega(\theta) = (1/2) \|\theta\|_2^2$, i.e., sum of squares of network's weights
- Since $\theta = w$, this becomes

$$\tilde{\mathcal{J}}(\boldsymbol{w}; \mathcal{X}, \boldsymbol{y}) = (\alpha/2) \boldsymbol{w}^\top \boldsymbol{w} + \mathcal{J}(\boldsymbol{w}; \mathcal{X}, \boldsymbol{y})$$

▲ロト ▲周 ト ▲ ヨ ト ▲ ヨ ト ・ シ へ つ ヘ

 As weights deviate from zero, activation functions become more nonlinear, which is higher risk of overfitting

Regularization Parameter Norm Penalties: L² Norm

Stephen Scott and Vinod Variyam

Introduction

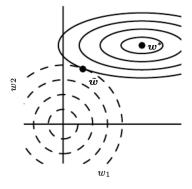

Measuring Performance

Regularization Causes of Overfitting Early Stopping Parameter Norm Penalties

Data Augmentation Multitask Learning Dropout Batch Normalization Others

Estimating Generalization Performance

Comparing Learning Aldoritans

- w^* is optimal for \mathcal{J} , 0 optimal for regularizer
- *J* less sensitive to w₁, so w
 w (optimal for *J*) closer to w₂
 axis than w₁

Regularization Parameter Norm Penalties: L¹ Norm

CSCE 496/896 Lecture 3: Regularization

Stephen Scott and Vinod Variyam

Regularization Data Augmentation

CSCE 496/896 Lecture 3: Regularization

Stephen Scott and Vinod Variyam

Introduction

Measuring Performance

Regularization Causes of Overfitting Early Stopping Parameter Norm Penalties Data Augmentation

Multitask Learning Dropout Batch Normalization Others

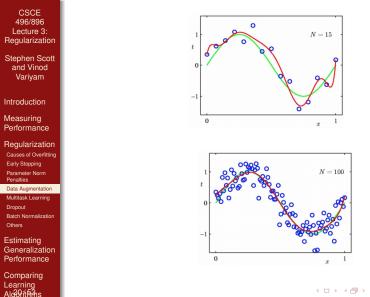

Estimating Generalization Performance

Comparing Learning Algorithms

- If *H* powerful and *X* small, then learner can choose some *h* ∈ *H* that fits idiosyncrasies or noise in data
- Deep ANNs would like to have at least thousands or tens of thousands of data points
- In classification of high-dimensional data (e.g., image classification), want learned classifier to tolerate transformations and noise
 - ⇒ Can artificially enlarge data set by duplicating existing instances and applying transformations
 - Translating, rotating, scaling
 - Don't change the class, e.g., "b" vs "d" or "6" vs "9"
 - Don't let duplicates lie in both training and testing sets
 - \Rightarrow Can also apply noise injection to input or hidden layers

Regularization Data Augmentation

Regularization Multitask Learning

Batch Normalization Others

Estimating Generalization Performance

Comparing Learning Alcoritems Addresses internal covariate shift, where changing parameters of layer *i* changes distribution of inputs to layer *i* + 1

 Related to z-normalization, where one subtracts sample mean and scales with standard deviation $\begin{array}{ll} \mbox{Input: Values of x over a mini-batch: $B = \{x_{1...m}\}$;} \\ \mbox{Parameters to be learned: γ, β} \\ \mbox{Output: } \{y_i = BN_{\gamma,\beta}(x_i)\} \\ \\ \mbox{$\mu_B \leftarrow \frac{1}{m}\sum_{i=1}^m x_i$ // mini-batch mean} \\ \mbox{$\sigma_B^2 \leftarrow \frac{1}{m}\sum_{i=1}^m (x_i - \mu_B)^2$ // mini-batch variance} \\ \mbox{$\widehat{x}_i \leftarrow \frac{x_i - \mu_B}{\sqrt{\sigma_B^2 + \epsilon}}$ // normalize} \\ \mbox{$y_i \leftarrow \gamma \widehat{x}_i + \beta \equiv BN_{\gamma,\beta}(x_i)$ // scale and shift} \end{array}$

Algorithm 1: Batch Normalizing Transform, applied to activation *x* over a mini-batch.

- γ , β learnable parameters
- Allows use of higher learning rates, possibly speeding convergence
- In some cases, reduces/eliminates need for dropout

CSCE 496/896 Lecture 3: Regularization

Stephen Scott and Vinod Variyam

Introduction

Measuring Performance

Regularization Causes of Overfitting Early Stopping Parameter Norm Penalties Data Augmentation Multitask Learning Dropout Batch Normalization Others

Estimating Generalization Performance

Comparing Learning Alcohitems

- **Parameter Tying:** If two learners are learning the same task but different scenarios (distributions, etc.), can tie their parameters together
 - If w^(A) are weights for task A and w^(B) are weights for task B, then can use regularization term
 Ω(w^(A), w^(B)) = ||w^(A) w^(B)||₂²
 - E.g., A is supervised and B is unsupervised
- **Parameter Sharing:** When detecting objects in an image, the same recognizer should apply invariant to translation
 - Train a single detector (subnetwork) for an object (e.g., cat) by training full network on multiple images with translated cats, where the cat detector subnets share parameters (single copy, used multiple times)

Regularization

Estimating Generalization Performance Setting Goals

Confidence Intervals

Comparing Learning Algorithms

Other Performance Measures

- Before setting up an experiment, need to understand exactly what the goal is
 - Estimate the generalization performance of a hypothesis
 - Tuning a learning algorithm's parameters
 - Comparing two learning algorithms on a specific task
 - Etc.
- Will never be able to answer the question with 100% certainty
 - Due to variances in training set selection, test set selection, etc.
 - Will choose an estimator for the quantity in question, determine the probability distribution of the estimator, and bound the probability that the estimator is way off
 - Estimator needs to work regardless of distribution of training/testing data

Estimating Generalization Performance Setting Goals

CSCE 496/896 Lecture 3: Regularization

Nebraska

Stephen Scott and Vinod Variyam

Introduction

Measuring Performance

Regularization

Estimating Generalization Performance Setting Goals

Confidence Intervals

Comparing Learning Algorithms

Other Performance Measures Need to note that, in addition to statistical variations, what we determine is limited to the application that we are studying

- E.g., if ANN₁ better than ANN₂ on speech recognition, that means nothing about video analysis
- In planning experiments, need to ensure that training data not used for evaluation
 - I.e., don't test on the training set!
 - Will bias the performance estimator
 - If using data augmentation, don't let duplicates lie in both training and testing sets
 - Also holds for **validation set** used for early stopping, tuning parameters, etc.
 - Validation set serves as part of training set, but not used for model building

How can we justify approximation?

Consider set of iid random variables Y_1, \ldots, Y_N , all from **arbitrary** probability distribution with mean μ and finite variance σ^2 . Define sample mean $\overline{Y} \equiv (1/N) \sum_{i=1}^n Y_i$

 \overline{Y} is itself a random variable, i.e., result of an experiment (e.g., $error_S(h) = r/N$)

Central Limit Theorem: As $N \to \infty$, the distribution governing \bar{Y} approaches normal distribution with mean μ and variance σ^2/N

Thus the distribution of $error_{S}(h)$ is approximately normal for large *N*, and its expected value is $error_{D}(h)$

(**Rule of thumb:** $N \ge 30$ when estimator's distribution is binomial; might need to be larger for other distributions)

If $p + t_{c,K-1} s_p < 0$ our assertion that L^1 has less error than L^2 is supported with confidence c

So if *K*-fold CV used, compute *p*, look up $t_{c,K-1}$ and check if $p < -t_{c,K-1} s_p$

One-sided test; says nothing about L^2 over L^1

Caveat

- Say you want to show that learning algorithm L^1 performs better than algorithms L^2, L^3, L^4, L^5
- If you use *K*-fold CV to show superior performance of L¹ over each of L²,..., L⁵ at 95% confidence, there's a 5% chance each one is wrong
- ⇒ There's an over 18.5% chance that at least one is wrong
- \Rightarrow Our overall confidence is only just over 81%
 - Need to account for this, or use more appropriate test

Confusion Matrices ROC Curves Precision-Recall Curves 44 / 53

- So far, we've looked at a single error rate to compare hypotheses/learning algorithms/etc.
- This may not tell the whole story:
 - 1000 test examples: 20 positive, 980 negative
 - h¹ gets 2/20 pos correct, 965/980 neg correct, for accuracy of (2 + 965)/(20 + 980) = 0.967
 - Pretty impressive, except that always predicting negative yields accuracy = 0.980
 - Would we rather have h^2 , which gets 19/20 pos correct and 930/980 neg, for accuracy = 0.949?
 - Depends on how important the positives are, i.e., frequency in practice and/or cost (e.g., cancer diagnosis)

Confusion Matrices ROC Curves Precision-Recall Curves 45 / 53 Break down error into type: true positive, etc.

	Predicted Class				
True Class	Positive	Negative	Total		
Positive	<i>tp</i> : true positive	fn : false negative	p		
Negative	<i>fp</i> : false positive	tn : true negative	n		
Total	<i>p'</i>	<i>n'</i>	N		

- Generalizes to multiple classes
- Allows one to quickly assess which classes are missed the most, and into what other class

Precision-Recall Curves 46 / 53

- Consider classification via ANN + linear threshold unit
- Normally threshold *f*(*x*; *w*, *b*) at 0, but what if we changed it?
- Keeping w fixed while changing threshold = fixing hyperplane's slope while moving along its normal vector

- Get a set of classifiers, one per labeling of test set
- Similar situation with any classifier with confidence value, e.g., probability-based

Precision-Recall Curves 49/53

- The **convex hull** of the ROC curve yields a collection of classifiers, each optimal under different conditions
 - If FP cost = FN cost, then draw a line with slope |N|/|P| at (0,1) and drag it towards convex hull until you touch it; that's your **operating point**
 - Can use as a classifier any part of the hull since can randomly select between two classifiers

Precision-Recall Curves 51 / 53

- What is the worst possible ROC curve?
- One metric for measuring a curve's goodness: area under curve (AUC):

$$\frac{\sum_{x_+ \in P} \sum_{x_- \in N} I(h(x_+) > h(x_-))}{|P| |N|}$$

- i.e., rank all examples by confidence in "+" prediction, count the number of times a positively-labeled example (from P) is ranked above a negatively-labeled one (from N), then normalize
 - What is the best value?
 - Distribution approximately normal if |P|, |N| > 10, so can find confidence intervals
 - Catching on as a better scalar measure of performance than error rate
- Possible (though tricky) with multi-class problems

 As with ROC, vary threshold to trade precision and recall

- Can compare curves based on containment
- More suitable than ROC for large numbers of negatives

• Use F_{β} -measure to combine at a specific point, where β weights precision vs recall:

$$F_{\beta} \equiv (1 + \beta^2) \frac{\text{precision} \cdot \text{recall}}{(\beta^2 \cdot \text{precision}) + \text{recal}}$$
